intro - introduction to file formats

DESCRIPTION

This section outlines the formats of various files. The C structure declarations for the file formats are given where applicable. Usually, the header files containing these structure declarations can be found in the directories /usr/include or /usr/include/sys. For inclusion in C language programs, however, the syntax #include <filename.h> or #include <sys/filename.h> should be used.

April 1990 - 1 - Version 5.0

a.out - assembler and link editor output

SYNOPSIS

#include <a.out.h>

DESCRIPTION

a.out is the output file format of the assembler as(1) and the link editor ld(1). Both programs make a.out executable if there were no errors and no unresolved external references. The debugger uses the a.out file to provide symbolic information to the user.

IRIX and the MIPS compilers use a file format that is similar to standard AT&T System V COFF (common object file format). For more information, see the Assembly Language Programmer's Guide.

The MIPS File Header definition is based on the System V header file filehdr.h with the following changes (also see filehdr (4)):

- The symbol table file pointer, f_symptr, and the number
 of symbol table entries f_nsyms, now specify the file
 pointer and the size of the Symbolic Header respectively.
- All tables that specify symbolic information have their file pointers and number of entries in the Symbolic Header.

The Optional Header definition has the same format as the System V header file *aouthdr.h* (the "standard" (pre-COFF) UNIX system a.out header) except the following fields have been added: *bss_start*, *gprmask*, *cprmask*, and *gp value*.

The Section Header definition has the same format as the System V header file *scnhdr.h*, except the line number fields (*s_lnnoptr* and *s_nlnno*) are used for gp tables (see *scnhdr*(4)).

The MIPS relocation information definition is similar to that in Berkeley 4.3 UNIX, which has "local" relocation types (see *reloc*(4)). Also see the section entitled **Section Relocation Information** in the *Assembly Language Programmer's Guide* for more detailed information.

For more information about System V COFF, refer to the AT&T UNIX System V Support Tools Guide.

The MIPS file format follows this scheme:

- File Header
- Optional Headers
- Section Headers
- Section Data—includes text, read-only data, large data, 8
 and 4-byte literal pools, small data, small bss (0 size),
 large bss (0 size), and shared library information.
- Section Relocation Information—includes text, read-only data, large data, 8 and 4-byte literal pools, and small data.
- Global Pointer (GP) Tables—missing if relocation information is not saved.
- Symbolic Header—missing if fully stripped.
- Line Numbers—created only if debugging is on, and missing if stripped of non-globals or fully stripped.
- Procedure Descriptor Table—missing if fully stripped.
- Local Symbols—missing if stripped of non-globals or if fully stripped.
- Optimization Symbols—created only if debugging is on, and missing if stripped of non-globals or fully stripped.
- Auxiliary Symbols—created only if debugging is on, and missing if stripped of non-globals or fully stripped.
- Local Strings—missing if stripped of non-globals or if fully stripped.
- External Strings—missing if fully stripped.
- Relative File Descriptor—missing if stripped of nonglobals or if fully stripped.
- File Descriptors—missing if stripped of non-globals or if fully stripped.
- External Symbols—missing is fully stripped.

The Section Data

MIPS files are represented in several sections: .text, .rdata (read-only data), .data (data), .sdata (small data), .lit8 (8-byte literal pool), .lit4 (4-byte literal pool), .sbss (small block started by storage), .bss (block started by storage), .init (initialization), and .lib (shared library references).

Generally only sections actually needed in an a.out file are present in the file.

The .text section contains the machine instructions that are to be executed; the .rdata, .data, .sdata, .lit8, and .lit4 sections contain initialized data; the .sbss and .bss sections reserve space for ininitialized data that is created by the kernel loader for the program before execution and filled with zeros.

The .init section contains shared library interface initialization information. The .lib section contains references to the shared libraries this a.out file uses.

April 1990 - 3 - Version 5.0

acct - per-process accounting file format

SYNOPSIS

#include <sys/acct.h>

DESCRIPTION

Files produced as a result of calling acct(2) have records in the form defined by $\langle sys/acct.h \rangle$, whose contents are:

```
typedef ushort comp_t;
                            /* "floating point" */
                   /* 13-bit fraction, 3-bit exponent */
struct
        acct
                              /* Accounting flag */
        char
                ac_flag;
        char
                ac_stat;
                              /* Exit status */
        ushort ac uid;
                              /* Accounting user ID */
        ushort ac_gid;
                              /* Accounting group ID */
        dev_t ac_tty;
                              /* control typewriter */
        time_t ac_btime;
                              /* Bcginning time */
        comp_t ac_utime;
                              /* acctng user time in clock ticks */
        comp_t ac_stime;
                              /* acctng system time in clock ticks */
                              /* acctng elapsed time in clock ticks */
        comp_t ac_etime;
        comp_t ac_mem;
                              /* memory usage in clicks */
        comp_t ac_io;
                              /* chars trnsfrd by read/write */
        comp_t ac_rw;
                              /* number of block reads/writes */
        char
                ac_comm[8]; /* command name */
};
                              acctbuf;
extern struct
                acct
                              *acctp; /* inode of accounting file */
extern struct inode
#define AFORK 01
                              /* has executed fork, but no exec */
#define ASU
                              /* used super-user privileges */
#define ACCTF 0300
                              /* record type: 00 = acct */
```

In ac_flag, the AFORK flag is turned on by each fork(2) and turned off by an exec(2). The ac_comm field is inherited from the parent process and is reset by any exec. Each time the system charges the process with a clock tick, it also adds to ac mem the current process size, computed as follows:

(data size) + (text size) / (number of in-core processes using text)

The value of $ac_mem/(ac_stime + ac_utime)$ can be viewed as an approximation to the mean process size, as modified by text sharing.

The structure acct, which resides with the source files of the accounting commands, represents the total accounting format used by the various accounting commands:

```
/*
         * total accounting (for acct period), also for day
         */
         struct tacct {
               uid_t
                              ta_uid;
                                           /* userid */
               char
                              ta_name[8]; /* login name */
                              ta_cpu[2]; /* cum. cpu time, p/np (mins) */
               float
                              ta_kcore[2]; /* cum kcore-minutes, p/np */
               float
                              ta_con[2]; /* cum. connect time, p/np, mins */
               float
               float
                              ta_du;
                                          /* cum. disk usage */
                                          /* count of processes */
               long
                              ta_pc;
                                           /* count of login sessions */
               unsigned short ta_sc;
               unsigned short ta_dc;
                                        /* count of disk samples */
                                          /* fee for special services */
               unsigned short ta_fee;
         };
SEE ALSO
         acct(2), exec(2), fork(2) in the Programmer's Reference Manual.
         acct(1M) in the System Administrator's Reference Manual.
```

acctcom(1) in the User's Reference Manual.

BUGS

The ac_mem value for a short-lived command gives little information about the actual size of the command, because ac_mem may be incremented while a different command (e.g., the shell) is being executed by the process.

April 1990 - 2 - Version 5.0

aliases – aliases file for sendmail

SYNOPSIS

/usr/lib/aliases

DESCRIPTION

This file describes user id aliases used by /usr/lib/sendmail. It is formatted as a series of lines of the form

name: name_1, name2, name_3, . . .

The *name* is the name to alias, and the *name_n* are the aliases for that name. Lines beginning with white space are continuation lines. Lines beginning with "#" are comments.

Aliasing occurs only on local names. Loops can not occur, since no message will be sent to any person more than once.

After aliasing has been done, local and valid recipients who have a ".forward" file in their home directory have messages forwarded to the list of users defined in that file.

This is only the raw data file; the actual aliasing information is placed into a binary format in the files /usr/lib/aliases.dir and /usr/lib/aliases.pag using the program newaliases(1). A newaliases command should be executed each time the aliases file is changed for the change to take effect.

SEE ALSO

newaliases(1), sendmail(1M) SENDMAIL Installation and Operation Guide. SENDMAIL: An Internetwork Mail Router.

BUGS

Because of restrictions in dbm(3B) a single alias cannot contain more than about 1000 bytes of information. You can get longer aliases by "chaining"; that is, make the last name in the alias be a dummy name which is a continuation alias.

ar - archive (library) file format

SYNOPSIS

#include <ar.h>

DESCRIPTION

The archive command *ar* combines several files into one. Archives are used mainly as libraries to be searched by the link-editor *ld*.

A file produced by ar has a magic string at the start, followed by the constituent files, each preceded by a file header. The magic number and header layout as described in the include file are:

```
#define ARMAG "!<arch>\n"
#define SARMAG 8
#define ARFMAG "'\n"
struct ar_hdr
       char
                 ar_name[16];
       char
                 ar_date[12];
       char
                 ar_uid[6];
       char
                 ar_gid[6];
       char
                 ar_mode[8];
       char
                 ar_size[10];
       char
                 ar_fmag[2];
};
typedef struct ar_hdr ARHDR;
```

The name is a blank-padded string. The *ar_fmag* field contains ARFMAG to help verify the presence of a header. The other fields are left-adjusted, blank-padded numbers. They are decimal except for *ar_mode*, which is octal. The date is the modification date of the file at the time of its insertion into the archive.

Each file begins on a even (0 mod 2) boundary; a new-line is inserted between files if necessary. Nevertheless the size given reflects the actual size of the file exclusive of padding.

There is no provision for empty areas in an archive file.

The encoding of the header is portable across machines. If an archive contains printable files, the archive itself is printable.

SEE ALSO

```
ar(1), ld(1), nm(1)
```

BUGS

File names lose trailing blanks. Most software dealing with archives takes even an included blank as a name terminator.

autologin - set autologin user identity

SYNOPSIS

/etc/autologin

DESCRIPTION

/etc/autologin is an ASCII file containing the login user name to be used when autologin is enabled. The file is used by getty(1M) and login(1) when automatically initiating a terminal session on the graphics console.

FILES

/etc/autologin

SEE ALSO

getty(1M),

login(1) in the User's Reference Manual.

April 1990 - 1 - Version 5.0

cftime – language specific strings

DESCRIPTION

The programmer can create one printable file per language. These files must be kept in a special directory /lib/cftime. If this directory does not exist, the programmer should create it. The contents of these files are:

- abbreviated month names (in order)
- month names (in order)
- abbreviated weekday names (in order)
- weekday names (in order)
- default strings that specify formats for local time (%x) and local date (%X).
- default format for cftime, if the argument for cftime is zero or null.
- AM (ante meridian) string
- PM (post meridian) string

Each string is on a line by itself. All white space is significant. The order of the strings in the above list is the same order in which the strings appear in the file shown below.

EXAMPLE

```
/lib/cftime/usa_english
```

April 1990 - 2 - Version 5.0

core - format of core image file

SYNOPSIS

#include <core.out.h>

DESCRIPTION

The IRIX system writes out a core image of a terminated process when any of various errors occur. See *signal(2)* for the list of reasons; the most common are memory violations, illegal instructions, bus errors, and usergenerated quit signals. The core image is called *core* and is written in the process's working directory (provided it can be; normal access controls apply). A process with an effective user ID different from the real user ID will not produce a core image.

The format of the core image is defined by **<core.out.h>.** It consists of a header, maps, descriptors, and section-data.

The header data includes the process name (as in ps(1)), the signal that caused the core-dump, the descriptor array, and the corefile location of the map array.

Each descriptor defines the length of useful process data. One descriptor defines the general-purpose registers at the time of the core-dump for example. The data is present in the core image at the file-location given in the descriptor only if the **IVALID** flag is set in the descriptor.

Each map defines the virtual address and length of a section-of-the-process at the time of the core-dump. The data is present in the core image at the file-location given in the descriptor only if the **VDUMPED** flag is set in the map. The process' stack, and data sections are normally written in the core image. The process' text is not normally written in the core image.

NOTE

Core image format designed by Silicon Graphics, Inc.

SEE ALSO

edge(1), dbx(1), ps(1), setuid(2), signal(2).

cpio - format of cpio archive

DESCRIPTION

The header structure, when the -c option of cpio(1) is not used, is:

```
struct {
                    h magic,
          short
                    h_dev;
          ushort
                    h_ino,
                    h_mode,
                    h_uid,
                    h_gid;
          short
                    h_nlink,
                    h rdev,
                    h mtime[2],
                    h_namesize,
                    h filesize[2];
                    h_name[h_namesize rounded to word];
          char
} Hdr;
```

When the -c option is used, the *header* information is described by:

```
sscanf(Chdr,"%60%60%60%60%60%60%60%60%11lo%60%11lo%s", &Hdr.h_magic, &Hdr.h_dev, &Hdr.h_ino, &Hdr.h_mode, &Hdr.h_uid, &Hdr.h_gid, &Hdr.h_nlink, &Hdr.h_rdev, &Longtime, &Hdr.h_namesize,&Longfile,Hdr.h_name);
```

Longtime and Longfile are equivalent to $Hdr.h_mtime$ and $Hdr.h_filesize$, respectively. The contents of each file are recorded in an element of the array of varying length structures, archive, together with other items describing the file. Every instance of h_magic contains the constant 070707 (octal). The items h_dev through h_mtime have meanings explained in stat(2). The length of the null-terminated path name h_name , including the null byte, is given by $h_namesize$.

The last record of the *archive* always contains the name TRAILER!!!. Special files, directories, and the trailer are recorded with $h_filesize$ equal to zero.

SEE ALSO

```
stat(2). cpio(1), find(1) in the User's Reference Manual.
```

cshrc - system-wide csh initialization command file

DESCRIPTION

The file /etc/cshrc contains a list of commands to be invoked whenever a user logs into the system with csh(1) as their login shell. These commands are executed before those in the .cshrc and .login files in the home directory of the user.

FILES

/etc/cshrc

SEE ALSO

csh(1).

dbg, debug - the debug file system

SYNOPSIS

#include <sys/types.h>
#include <sys/fs/dbfcntl.h>

DESCRIPTION

The debug file system, normally mounted under /debug, provides an interface to running processes that may be used by debuggers such as dbx. The "files" of this file system are of the form |debug| < pid >, where < pid > is the process id of a running process. These files actually consume no disk space, and are only convenient handles by which a debugger can attach to a process. The debugger does so by opening the desired /debug file with the open(2) system call. The debugger may perform various fcntl(2) commands to the process; for example, to suspend and restart the process. When the process is suspended, ordinary seek(2), read(2), and write(2) system calls will access the process' address space.

The statfs(2) system call will return valid information concerning the dbg file system. The total and free blocks as reported by df(1) respectively represent the total virtual memory (real memory plus swap space) available and currently free.

The following fcntl(2) codes are recognized by dbg files. An optional argument may be supplied to the call; the form of the argument varies with the request and will be described where appropriate.

DFCSTOP

Suspend the process as soon as possible. This usually leaves the process in the stopped state; this can be verified with ps(1). However, sleeping processes remain on the sleep queue and are marked as suspended, and are therefore can be considered stopped.

DFCWSTOP

Wait for the process to stop. This is useful after setting breakpoints, system call trace masks, etc.

DFCRUN

Resume process execution after process is suspended. The argument specifies how pending signals are to be treated. If this is CLEARNO-SIG, no signals are cleared; if this is CLEARCURSIG, only the current signal is cleared; or if this is CLEARALLSIG, all pending signals are cleared. If the value is between 1 and NSIG inclusive, clear all pending signals and continue with the given signal.

DFCSSTEP

Resume process execution, but stop after executing a single machine instruction. The argument is the same as that of the DFCRUN request.

DFCCSIG

Clear the highest signal pending. This request takes no arguments. (This request is really not too useful, since the argument to DFCRUN or DFCSSTEP provides for more precise signal control.)

DFCKILL

Send a signal to the process. The argument is a an unsigned int representing the signal number.

DFCSMASK

Sets the signal trace mask. The argument is a pointer to a long indicating whether the process should stop upon receiving specified signals. To trace signal s, set (1 << (s-1)) in the signal mask.

DFCGMASK

Retrieve the signal trace mask. The argument is a pointer to a long in which to store the current signal mask.

DFCSENTRYMASK

Sets the system call entry mask. The argument is a pointer to an array of SYSMASKLEN long values indicating whether the process should stop prior to executing certain system calls. For example, to trace system call *syscallno* the code would resemble something like:

```
#include <sys/user.h> /* defines SYSMASKLEN */
#include <sys/fs/dbfcntl.h>
#define BITSPERLONG 32
long entrymask[SYSMASKLEN]
.
.
```

entrymask[syscallno/BITSPERLONG] ⊨ (1 << (syscallno%BITSPERLONG)); fcntl(fd, DFCSENTRYMASK, &entrymask);

Note that the system call numbers as defined in /usr/include/sys.s are relative to a large offset, SYSVoffset. This offset should be subtracted from the actual system call number before setting the bit in the mask.

DFCGENTRYMASK

Sets the system call exit mask. As above, the argument is a pointer to an array of SYSMASKLEN long values; however, this indicates that the process should stop immediately after executing specified system calls.

DFCABORT

Abort the system call in progress. If the process is stopped prior to executing a system call (see DFCSENTRYMASK above), this request will cause the signal call to return prematurely with an EINTR error code when the process is resumed.

DFCSEXEC

Have the process stop after an exec(2) system call. This is useful for stopping the process to set initial breakpoints.

DFCREXEC

No longer stop the process after an exec(2) system call.

DECGETREGS

Retrieve the processor registers and signal handlers. The argument should be a pointer to an array of NPTRC_REGS unsigned integers. The general purpose processor registers, floating point registers, signal handlers, and special purpose control registers will be deposited in this array. NPTRC_REGS, as well as a layout of the registers in the array, is defined in the header file /usr/include/sys/ptrace.h.

DFCPUTREGS

Write the processor registers. The argument should be a pointer to an array of NPTRC_REGS unsigned integers. The contents of the array are copied to the appropriate register locations. Note that the signal handlers and read-only control registers are not modified.

DFCGETPRINFO

Retrieve some useful information about the process. The argument to this request should be a pointer to a buffer of sizeof(struct procinfo) bytes. This structure, defined in /usr/include/sys/fs/dbfcntl.h, contains useful information concerning the process status.

DFCGETPR

Get the entire contents of the process table entry corresponding to the process. The argument supplied should be a pointer to a buffer of at least sizeof(struct proc) bytes. (Due to the lack of portability of this call, the DFCGETPRINFO request is preferred.)

DFCOPENT

If the given argument is zero, return the file descriptor corresponding to the text region of the process. If the given argument is non-zero, interpret this value as a virtual address of the process. Return the file descriptor corresponding to the region containing this address. This call may be used to locate symbol tables of the process.

DFCEXCLU

If the given argument is zero, make the text region "private" and writable. Otherwise, make the region corresponding to the given address private. (Note: the first write to a read-only region will have the same affect and thus this call is usually not necessary.)

DIAGNOSTICS

These return codes are relevant to most system calls applied to dbg files.

[ENOENT] The process no longer exists or is in the zombie state.

[EACCES] The caller does not have permission to trace the process.

[EIO] The process should be stopped before attempting this

call.

[EINVAL] An argument to this call was invalid.

[EFAULT] An address supplied by the user was invalid.

[EPERM] This operation is not allowed on a dbg file.

[EROFS] The *dbg* filesystem was mounted read only.

[ENOMEM] The kernel could not allocate enough memory to perform

this request.

dir - format of EFS directories

SYNOPSIS

#include <sys/fs/efs dir.h>

DESCRIPTION

A directory behaves exactly like an ordinary file, save that no user may write into a directory. The fact that a file is a directory is indicated by a bit in the flag word of its i-node entry [see *inode*(4)]. The EFS directory format supports variable length names of up to 255 characters.

DIRECTORY BLOCKS

Each EFS directory is segmented into directory blocks defined by the following data structure:

Each directory block is subdivided into three separate areas: a header, an array of entry offsets and an array of directory entries. The system restricts directory entries to short boundaries and stores offsets in the directory block compacted by shifting them right by one.

The header area contains a *magic* number to identify the block as being a directory block. If the *magic* number is incorrect, the operating system will refuse to manipulate the directory, thus avoiding further corruption.

The array of entry offsets immediately follows the header and is sized according to the directories contents and contains compacted offsets which point to each directory entry. The number of entry offsets available is kept in *slots*. The *firstused* field contains a compacted offset which positions the first byte of the directory entries.

The space between the end of the entry array and the beginning of the directory entries (firstused) is free space which the system uses for allocating new directory entries and entry offsets. The system keeps the free space in a directory block compacted by coalescing holes created by entry removal. When a directory entry is removed, the system adjusts the entry offsets

for all entries that move. Also, the entry offset for the removed entry is zeroed. If the removed entry was the last in the entry offset array, the number of *slots* is reduced. Directory entries never change which entry offset they use.

DIRECTORY ENTRIES

Directory entries have the following structure:

```
struct efs_dent {
    union {
        ulong 1;
        ushort s[2];
    } ud_inum;
    unchar d_namelen;
    char d_name[3];
};
```

The <u>d_name</u> field is actually of variable size, depending upon the value contained in <u>d_namelen</u>. The system pads out the directory entry to insure that it begins on a short boundary in the directory block. The <u>ud_inum</u> field contains the entries inode number.

fs(4), inode(4).

April 1990 - 2 - Version 5.0

dirent – file system independent directory entry

SYNOPSIS

#include <sys/dirent.h>

DESCRIPTION

Different file system types may have different directory entries. The *dirent* structure defines a file system independent directory entry, which contains information common to directory entries in different file system types. A set of these structures is returned by the *getdents*(2) system call.

The dirent structure is defined below.

The d_ino is a number which is unique for each file in the file system. The field d_off is an opaque offset (i.e., not necessarily in bytes) of the next directory entry in the actual file system directory. The field d_name is the beginning of the character array giving the name of the directory entry. This name is null terminated and may have at most MAXNAMLEN characters. This results in file system independent directory entries being variable length entities. The value of d_reclen is the record length of this entry. This length is defined to be the number of bytes between the current entry and the next one, so that it will always result in the next entry being on a long boundary.

directory(3X), getdents(2).

filehdr - file header for MIPS object files

SYNOPSIS

#include <filehdr.h>

DESCRIPTION

Every MIPS object file begins with a 20-byte header. The following C struct declaration is used:

```
struct filehdr
{
  unsigned short
                     f_magic; /* magic number */
                     f nscns;
                                 /* number of sections */
  unsigned short
                     f_timdat; /* time & date stamp */
  long
                     f_symptr; /* file pointer to symbolic header */
  long
  long
                     f_nsyms; /* sizeof(symbolic header) */
                     f_opthdr; /* sizeof(optional header) */
  unsigned short
  unsigned short
                     f_flags;
                                 /* flags */
};
```

 F_symptr is the byte offset into the file at which the symbolic header can be found. Its value can be used as the offset in fseek(3S) to position an I/O stream to the symbolic header. The UMIPS system optional header is 56-bytes. The valid magic numbers are given below:

MIPS object files can be loaded and examined on machines differing from the object's target byte sex. Therefore, for object file magic numbers, the byte swapped values have define constants associated with them:

```
#define SMIPSEBMAGIC 0x6001
#define SMIPSELMAGIC 0x6201
```

The value in f_{timdat} is obtained from the time(2) system call. Flag bits used in MIPS objects are:

```
#define F_RELFLG 0000001 /* relocation entries stripped */
#define F_EXEC 0000002 /* file is executable */
#define F_LNNO 0000004 /* line numbers stripped */
#define F_LSYMS 0000010 /* local symbols stripped */
```

SEE ALSO

time(2), fseek(3S), a.out(4).

efs - layout of the Extent file system

SYNOPSIS

```
#include <sys/param.h>
#include <sys/fs/efs.h>
```

DESCRIPTION

Every Extent file system storage volume has a common format for certain vital information. Every such volume is divided into a certain number of 512 byte long sectors, also called *basic blocks*. Basic block 0 is unused and is available to contain a bootstrap program or other information.

Basic block 1 is the *super-block*. The format of an Extent file system super-block is:

```
* Structure of the super-block for the Extent file system
*/
          efs {
struct
    * This portion is read off the volume
    long fs_sizc;
                              /* size of file system, in sectors */
                              /* bb offset to first cg */
    long fs_firstcg;
                              /* size of cylinder group in bb's */
    long fs_cgfsize;
                              /* bb's in inodes per cylinder group */
    short fs_cgisizc;
                              /* sectors per track */
    short fs sectors;
    short fs_heads; /* heads per cylinder */
    short fs_ncg;
                              /* # of groups in file system */
                              /* fs needs to be fsck'd */
    short fs_dirty;
                                        /* last super-block update */
                    fs_time;
    time t
    long fs_magic;/* magic number */
    char fs_fname[6];
                              /* file system name */
                              /* file system pack name */
    char fs_fpack[6];
                              /* size of bitmap in bytes */
    long fs_bmsize;
    long fs_tfree;
                              /* total free data blocks */
                              /* total free inodes */
    long fs_tinode;
    long fs_bmblock;
                              /* bitmap location */
    long fs_replsb;/* location of replicated superblock. */
                              /* space for expansion */
    char fs_spare[24];
                              /* checksum of volume portion of fs */
    long fs_chccksum;
     * The remainder of this structure, defined fully in <sys/fs/efs_sb.h>
     * is used by the operating system only.
     */
```

};

#define EFS_MAGIC 0x072959

Note that the struct efs that is defined in <*sys/fs/efs_sb.h*> contains more fields. The extra fields are used internally by the operating system, and are not discussed here. *fs_size* holds the size in basic blocks of the file system. This variable is filled in when the file system is first created with *mkfs*(1M).

fs_firstcg contains the basic block offset to the first cylinder group. There are fs_ncg cylinder groups contained in the file system. Each cylinder group is composed of fs_cgfsize basic blocks, of which fs_cgisize basic blocks are used for inodes.

fs_sectors, and fs_heads are used to specify the geometry of the underlying disk containing the file system. Note that fs_heads is in fact currently unused, and should not be relied upon.

fs_dirty is a flag which indicates if the file system needs to be checked by the fsck(1M) program. The fs_time field contains the time stamp of when the file system was last modified. fs_name holds the name of the file system (where it is mounted, more or less) while fs_fpack contains which volume this file system is. The fs_fpack field is singularly useless, but is provided for utility compatibility. fs_magic is used to tag the superblock of the file system as an Extent file system.

The fs_bmsize field contains, in bytes, the size of the data block bitmap. The data block bitmap is used for data block allocation. Each one in the bitmap indicates a free block. The $fs_bmblock$ field contains the location of the bitmap if it has been moved from its default location (basic block 2) because the file system has been constructed on a logical volume which has been extended (see growfs(lm)).

fs_tfree and fs_tinode contain the total free blocks and inodes, respectively. The fs_replsb field contains the location of a replicated superblock, if one exists

The fs spare field is reserved for future use.

Lastly, the *fs_checksum* variable holds a checksum of the above fields (not including itself).

During the *mount*(1M) of the file system, the *fs_dirty* and *fs_checksum* fields are examined. If *fs_dirty* is non-zero, or the *fs_checksum* variable does not match the systems computed checksum, then the file system must be cleaned with *fsck* before it can be mounted. If the file system is the *root* partition, then this check is ignored, as it is necessary to be able to run *fsck* on a dirty *root* from a dirty *root*. For the format of an inode and its flags, see *inode*(4).

fspec – format specification in text files

DESCRIPTION

It is sometimes convenient to maintain text files on the UNIX system with non-standard tabs, (i.e., tabs which are not set at every eighth column). Such files must generally be converted to a standard format, frequently by replacing all tabs with the appropriate number of spaces, before they can be processed by UNIX system commands. A format specification occurring in the first line of a text file specifies how tabs are to be expanded in the remainder of the file.

A format specification consists of a sequence of parameters separated by blanks and surrounded by the brackets <: and :>. Each parameter consists of a keyletter, possibly followed immediately by a value. The following parameters are recognized:

ttabs The t parameter specifies the tab settings for the file. The value of tabs must be one of the following:

- 1. a list of column numbers separated by commas, indicating tabs set at the specified columns;
- 2. a followed immediately by an integer n, indicating tabs at intervals of n columns;
- 3. a followed by the name of a "canned" tab specification.

Standard tabs are specified by t-8, or equivalently, t1,9,17,25, etc. The canned tabs which are recognized are defined by the tabs(1) command.

Ssize The s parameter specifies a maximum line size. The value of size must be an integer. Size checking is performed after tabs have been expanded, but before the margin is prepended.

mmargin The m parameter specifies a number of spaces to be prepended to each line. The value of margin must be an integer.

- d The d parameter takes no value. Its presence indicates that the line containing the format specification is to be deleted from the converted file.
- e The e parameter takes no value. Its presence indicates that the current format is to prevail only until another format specification is encountered in the file.

Default values, which are assumed for parameters not supplied, are t-8 and m0. If the s parameter is not specified, no size checking is performed. If the first line of a file does not contain a format specification, the above defaults are assumed for the entire file. The following is an example of a line containing a format specification:

If a format specification can be disguised as a comment, it is not necessary to code the **d** parameter.

April 1990 - 2 - Version 5.0

fstab - static information about filesystems

DESCRIPTION

The file /etc/fstab describes the filesystems used by the local machine. The system administrator can modify it with a text cditor. It is read by commands that mount, unmount and check the consistency of filesystems. The file consists of a number of lines of the form:

filesystem directory type options frequency pass

For example:

```
/dev/root / efs rw 0 0
```

Fields are separated by white space; a '#' as the first non-white character indicates a comment.

The entries from this file are accessed using the routines in *getmntent* (3), which returns a structure of the following form:

```
struct mntent {
    char *mnt_fsname; /* filesystem name */
    char *mnt_dir; /* filesystem path prefix */
    char *mnt_type; /* efs, nfs, dbg, or ignore */
    char *mnt_opts; /* rw, ro, hard, soft */
    int mnt_freq; /* dump frequency, in days */
    int mnt_passno; /* parallel fsck pass number */
};
```

This structure is defined in the <mntent.h> include file. To compile and link a program that calls *getmntent*(3), follow the procedures for section (3Y) routines as described in *intro*(3).

The *mnt_dir* field is the full path name of the directory to be mounted on. The *mnt_type* field determines how the *mnt_fsname* and *mnt_opts* fields will be interpreted. Here is a list of the filesystem types currently supported, and the way each of them interprets these fields:

```
efs mnt fsname must be a block special device (e.g., /dev/root).
```

dbg mnt fsname should be the /dcbug directory. See dbg(4).

nfs *mnt_fsname* is the path on the server of the directory to be served. (NFS option only).

If the *mnt_type* is specified as **ignore**, then the entry is ignored. This is useful to show disk partitions not currently used. *Mnt_freq* and *mnt_passno* are not supported.

The *mnt_opts* field contains a list of comma-separated option words. Some *mnt_opts* are valid for all filesystem types, while others apply to a specific type only.

Options valid on efs and nfs filesystems (the default is rw):

rw read/write.ro read-only.

noauto ignore this entry during a mount -a command, to allow

the definition of fstab entries for commonly-used filesys-

tems that should not be automatically mounted.

grpid causes a file created within the filesystem to have the

group-ID of its parent directory, not the creating process's

group-ID.

Options specific to efs filesystems (the default is fsck):

raw=path the filesystem's raw device pathname (e.g. /dev/rroot).

fsck fsck(1M) invoked with no filesystem arguments should

check this filesystem.

nofsck fsck(1M) should not check this filesystem by default.

Ibsize=n the number of bytes transferred in each read or synchro-

nous write operation.

The value assigned to the Ibsize option must be a power of two at least as large as NPBC (as defined in /usr/include/sys/param.h), and no larger than 64K. The current default for Ibsize is the largest power of two less than or equal to the size of one disk track. An invalid size will cause the mount to fail with the error EINVAL. Note that less than Ibsize bytes will be transferred if there are not Ibsize contiguous bytes of the addressed portion of the file on disk.

If the NFS option is installed, the following options are valid for **nf**s filesystems:

bg if the first attempt fails, retry in the background.

fg retry in foreground. (Default)

retry=n set number of mount failure retries to n. (Default =

10000)

rsize=n set read buffer size to n bytes. (Default = 8K)

wsize=n	set write buffer size to n bytes. (Default = $8K$)
timeo=n	sct NFS timeout to n tenths of a second. (Default = 7)
retrans=n	set number of NFS retransmissions to n . (Default = 4)
port=n	set server UDP port number to n . (Default = 2049)
hard	retry request until server responds. (Default)
soft	return error if server doesn't respond.
intr	allow hard mounts to be interrupted by uncaught fatal signals. (Default)
nointr	don't allow hard mounts to be interrupted.
acregmin=t	set the regular file minimum attribute cache timeout to t seconds. (Default = 3)
acregmax=t	set the regular file maximum attribute cache timeout to t seconds. (Dcfault = 60)
acdirmin=t	set the directory minimum attribute cache timeout to t seconds. (Default = 30)
acdirmax=t	set the directory maximum attribute cache timeout to t seconds. (Default = 60)
actimeo=t	set regular and directory minimum and maximum attribute cache timeouts to t seconds.
noac	no attribute caching.
private	do not flush delayed writes on last close of an open file, and use local file and record locking instead of a remote lock manager.

The bg option causes mount to run in the background if the server's mountd(1M) does not respond. Mount attempts each request retry=n times before giving up.

Once the filesystem is mounted, each nfs request made waits timeo=n tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When retrans=n retransmissions have been sent with no reply a soft mounted filesystem returns an error on the request and a hard mounted filesystem retries the request. Filesystems that are mounted rw (read-write) should use the hard option. The number of bytes in a read or write request can be set with the rsize and wsize options.

In the absence of client activity that would invalidate recently acquired file attributes, NFS holds attributes cached for an interval between acregmin and acregmax for regular files, and between acdirmin and acdirmax for directories. The actimeo option sets all attribute timeout constraints to a given number of seconds. The noac option disables attribute caching altogether.

The private option greatly improves write performance by caching data and delaying writes on the assumption that only this client modifies files in the remote filesystem. It should be used only if the greater risk of lost delayed-write data in the event of a crash is acceptable given better performance. Note that EFS uses caching strategies similar to private NFS, and that the system reduces the risk of data loss for all filesystems by automatically executing a partial sync (2) at regular intervals.

NOTES

The default *fstab* supplied with SGI systems contains the following entry for the /usr filesystem:

```
/dev/usr /usr efs rw.raw=/dev/rusr 0 0
```

The setup program MAKEDEV (see makedev(1M)) creates /dev/usr and /dev/rusr as links to partition 6 on the root disk. This is the normal disk usage; however, if you wish to set up a machine with the /usr filesystem residing elsewhere (for example, on a second disk or on a logical volume, described in lv(7M)), the mnt_fsname field must be changed to the full pathname of the device where the /usr filesystem actually resides. If present, the path specified by the raw option should also be changed to the corresponding full pathname. For example:

```
/dev/dsk/ips0dls7 /usr efs rw,raw=/dev/rdsk/ips0dls7 0 0
```

Note that if this is done, the /dev/usr and /dev/rusr devices created by MAK-EDEV will not point to the device containing the /usr filesystem, and they should not be referenced.

Caution: do not attempt to reconfigure a system with /usr in a non-default volume by manually recreating these /dev/usr and /dev/rusr links and leaving the fstab entry unchanged. While this would work in normal operation, it will lead to incorrect behaviour when installing new software.

FILES

/etc/fstab

fsck(1M), mount(1M), mtab(4) getmntent(3) if the NFS option is installed. Extensions by Silicon Graphics, Inc.

gettydefs - speed and terminal settings used by getty

DESCRIPTION

The /etc/gettydefs file contains information used by getty(1M) to set up the speed and terminal settings for a line. It supplies information on what the login(1) prompt should look like. It also supplies the speed to try next if the user indicates the current speed is not correct by typing a <break> character.

NOTE: Customers who need to support terminals that pass 8 bits to the system (as is typical outside the U.S.A.) must modify the entries in /etc/gettydefs as described in the WARNINGS section.

Each entry in /etc/gettydefs has the following format:

label# initial-flags # final-flags # login-prompt #next-label

Each entry is followed by a blank line. The various fields can contain quoted characters of the form b, n, c, etc., as well as nnn, where nnn is the octal value of the desired character. The various fields are:

lahel

This is the string against which *getty*(1M) tries to match its second argument. It is often the speed, such as 1200, at which the terminal is supposed to run, but it need not be (see below).

initial-flags

These flags are the initial *ioctl*(2) settings to which the terminal is to be set if a terminal type is not specified to *getty*(1M). The flags that *getty*(1M) understands are the same as the ones listed in /usr/include/sys/termio.h [see *termio*(7)]. Normally only the speed flag is required in the *initial-flags*. *getty*(1M) automatically sets the terminal to raw input mode and takes care of most of the other flags. The *initial-flag* settings remain in effect until *getty*(1M) executes *login*(1).

final-flags

These flags take the same values as the *initial-flags* and are set just before *getty*(1M) executes *login*(1). The speed flag is again required. The composite flag SANE takes care of most of the other flags that need to be set so that the processor and terminal are communicating in a rational fashion. The other two commonly specified *final-flags* are TAB3, so that tabs are sent to the terminal as spaces, and HUPCL, so that the line is hung up on the final close.

login-prompt This entire field is printed as the login-prompt. Unlike the above fields where white space is ignored (a space, tab or

new-line), they are included in the *login-prompt* field.

next-label

If this entry does not specify the desired speed, indicated by the user typing a *
break>* character, then *getty(1M)* will search for the entry with *next-label* as its *label* field and set up the terminal for those settings. Usually, a series of speeds are linked together in this fashion, into a closed set; for instance, 2400 linked to 1200, which in turn is linked to 300, which finally is linked to 2400.

If getty(1M) is called without a second argument, then the first entry of /etc/gettydefs is used, thus making the first entry of /etc/gettydefs the default entry. It is also used if getty(1M) can not find the specified label. If /etc/gettydefs itself is missing, there is one entry built into getty(1M) which will bring up a terminal at 300 baud.

It is strongly recommended that after making or modifying /etc/gettydefs, it be run through getty(1M) with the check option to be sure there are no errors.

FILES

/etc/gettydefs

SEE ALSO

getty(1M), termio(7) in the System Administrator's Reference Manual. ioctl(2) in the Programmer's Reference Manual. login(1), stty(1) in the User's Reference Manual.

WARNINGS

To support terminals that pass 8 bits to the system (also, see the BUGS section), modify the entries in the /etc/gettydefs file for those terminals as follows: add CS8 to *initial-flags* and replace all occurrences of SANE with the values: BRKINT IGNPAR ICRNL IXON OPOST ONCLR CS8 ISIG ICANON ECHO ECHOK

An example of changing an entry in /etc/gettydefs is illustrated below. All the information for an entry must be on one line in the file.

Original entry:

CONSOLE # B9600 HUPCL OPOST ONLCR # B9600 SANE IXANY TAB3 HUPCL # Console Login: # console

Modified entry:

CONSOLE # B9600 CS8 HUPCL OPOST ONLCR # B9600 BRKINT IGNPAR ICNRL IXON OPOST ONLCR CS8 ISIG ICANON ECHO ECHOK IXANY TAB3 HUPCL # Console Login: # console

This change will permit terminals to pass 8 bits to the system so long as the system is in MULTI-USER state. When the system changes to SINGLE-USER state, the *getty*(1M) is killed and the terminal attributes are lost. So to permit a terminal to pass 8 bits to the system in SINGLE-USER state, after you are in SINGLE-USER state, type (see *stty*(1)):

stty -istrip cs8

BUGS

8-bit with parity mode is not supported.

Aprii 1990 - 3 - Version 5.0

group – group membership file

DESCRIPTION

The /etc/group file contains for each group the following information:

- group name
- · encrypted password
- numerical group ID
- a comma separated list of all users allowed in the group

For example, the entry for the sys group is:

sys::0:root,bin,sys,adm

This is an ASCII file. The fields are separated by colons; each group is separated from the next by a new-line. If the password field is null, no password is demanded. A "*" in the password field locks the entry.

This file resides in the *letc* directory. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical group ID's to names.

YELLOW PAGES

If the NFS option is installed, a group file can have a line beginning with a plus (+), which means to incorporate entries from the Yellow Pages. There are two styles of + entries: All by itself, + means to insert the entire contents of the Yellow Pages group file at that point; +name means to insert the entry (if any) for name from the Yellow Pages at that point. If a + entry has a non-null password or group member field, the contents of that field will overide what is contained in the Yellow Pages. The numerical group ID field cannot be overridden.

A group file can also have a line beginning with a minus (–), these entries are used to disallow group entries. There is only one style of – entries: an entry that consists of -name means to disallow any subsequent entry (if any) for name. These entries will be disallowed regardless of whether the subsequent entry comes from the Yellow Pages or the local group file.

For example, if the following entries

```
-oldproj
```

+myproject:::bill, steve

٠.

appear at the end of a group file, then the group *oldproj* will be ignored if it appears after the entry *-oldproj*. Also, the group *myproject* will have members *bill* and *steve*, and the password and group ID of the Yellow Pages entry for the group *myproject*. All the groups listed in the Yellow Pages will be pulled in and placed after the entry for *myproject*.

The *passwd*(1) command won't change group passwords. Sun Microsystems (YP version)

hosts - host name data base

DESCRIPTION

The /etc/hosts file contains information regarding the known hosts on the network. For each host a single line should be present with the following information:

Internet address official host name aliases

Items are separated by any number of blanks and/or tab characters. A "#" indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.

This file must include entrics for the machine's network interfaces, the "localhost" address and a few important machines on the local network. *ifconfig*(1M) uses this file when assigning addresses to the network interfaces.

By default, this file is used by *gethostbyname* (3N) and *gethostbyaddr* (3N) only when the Yellow Pages or the Berkeley name server (*named* (1M)) are not enabled. The system can be configured to use YP, *named*, and/or this file, as described in *resolver* (4) and the *Network Communications Guide*.

If the host is not connected to any network, the file should contain an entry defining the hostname as an alias for the "localhost" entry. For example, if the hostname is IRIS, the /etc/hosts file should contain this line:

127.1 localhost IRIS

Sites connected to the Internet should configure the system to use the name server. This file may be created from the official host data base maintained at the Network Information Center (NIC), though local changes may be required to bring it up to date regarding unofficial aliases and/or unknown hosts. The host data base maintained at NIC is incomplete.

Network addresses are specified in the conventional "." (dot) notation using the *inet_addr()* routine from the Internet address manipulation library, *inet(3N)*. Host names may contain any printable character other than a field delimiter, newline, or comment character.

hosts.equiv - list of trusted hosts

DESCRIPTION

The *letclhosts.equiv* file contains a list of trusted hosts. When an rlogin(1C), rcp(1C), rdist(1C), or rsh(1C) request from such a host is made, and the initiator of the request is in *letclpasswd*, then, no further validity checking is done. That is, rlogin does not prompt for a password, and rcp, rdist, and rsh complete successfully. So a remote user is "equivalenced" to a local user with the same user name when the remote user is in *hosts.equiv*.

The format of *hosts.equiv* is a list of host names, as in this example:

bonnie.sgi.com clyde.sgi.com

A line consisting of a simple host name means that anyone logging in from that host is trusted. Programs scan *hosts.equiv* linearly, and stop at the first hit.

The .rhosts file has the same format as hosts.equiv. When user XXX executes rlogin or rsh, the .rhosts file from XXX's home directory is conceptually concatenated onto the end of hosts.equiv for permission checking. In the special case when the user is root, then only the /.rhosts file is checked.

If an entry in a local user's .rhosts file contains a remote host name and a user name separated by white space, the remote user is allowed to log in as the local user. Thus the entry

bonnie.sgi.com faye

in warren's .rhosts allows faye to log in from bonnie as warren. If this entry was placed in clyde's /etc/hosts.equiv, then faye could login as anyone who is in clyde's /etc/passwd file.

inittab - script for the init process

DESCRIPTION

The /etc/inittab file supplies the script to *init*'s role as a general process dispatcher. The process that constitutes the majority of *init*'s process dispatching activities is the line process /etc/getty that initiates individual terminal lines. Other processes typically dispatched by *init* are daemons and the shell.

The *inittab* file is composed of entries that are position dependent and have the following format:

id:rstatc:action:process

Each entry is delimited by a newline; however, a backslash (\setminus) preceding a newline indicates a continuation of the entry. Up to 512 characters per entry are permitted. Comments may be inserted in the *process* field using the sh(1) convention for comments. Comments for lines that spawn gettys are displayed by the who(1) command. It is expected that they will contain some information about the line such as the location. There are no limits (other than maximum entry size) imposed on the number of entries within the *inittab* file. The entry fields are:

id This field, of up to four characters, is used to uniquely identify an entry.

rstate

This defines the *run-level* in which this entry is to be processed. Run-levels effectively correspond to a configuration of processes in the system. That is, each process spawned by init is assigned a run-level or run-levels in which it is allowed to exist. The runlevels are represented by the letter s (or S), or a number ranging from 0 through 6. As an example, if the system is in run-level 1, only those entries having a 1 in the rstate field will be processed. When init is requested to change run-levels, all processes which do not have an entry in the rstate field for the target run-level will be sent the warning signal (SIGTERM) and allowed a grace period (see init(1M) for the length of this grace period), before being forcibly terminated by a kill signal (SIGKILL). The rstate field can define multiple run-levels for a process by selecting more than one run-level in any combination from 0-6, s and S. If no run-level is specified, then the process is assumed to be valid at all run-levels. There are three other values, a, b and c, which can appear in the rstate field, even though they are not true run-levels. Entries which have these characters in the *rstate* field are processed only when the telinit [see init(1M)] process requests them to be run (regardless of the current run-level of the system). They differ

from run-levels in that init can never enter run-level a, b or c. Also, a request for the execution of any of these processes does not change the current run-level. Furthermore, a process started by an a, b or c command is not killed when init changes levels. They are only killed if their line in /etc/inittab is marked off in the action field, their line is deleted entirely from /etc/inittab, or init goes into the SINGLE USER state.

action

Key words in this field tell *init* how to treat the process specified in the *process* field. The actions recognized by *init* are as follows:

respawn

If the process does not exist then start the process, do not wait for its termination (continue scanning the *inittab* file), and when it dies restart the process. If the process currently exists then do nothing and continue scanning the *inittab* file.

wait

Upon *init*'s entering the *run-level* that matches the entry's *rstate*, start the process and wait for its termination. All subsequent reads of the *inittab* file while *init* is in the same *run-level* will cause *init* to ignore this entry.

once

Upon *init*'s entering a *run-level* that matches the entry's *rstate*, start the process, do not wait for its termination. When it dies, do not restart the process. If upon entering a new *run-level*, where the process is still running from a previous *run-level* change, the program will not be restarted.

boot

The entry is to be processed only at *init*'s boot-time read of the *inittab* file. *Init* is to start the process, not wait for its termination; and when it dies, not restart the process. In order for this instruction to be meaningful, the *rstate* should be the default or it must match *init*'s *run-level* at boot time. This action is useful for an initialization function following a hardware reboot of the system.

bootwait

The entry is to be processed the first time *init* goes from single-user to multi-user state after the system is booted. (If **initdefault** is set to 2, the process will run right after the boot.) *Init* starts the process, waits for its termination and, when it dies, does not restart the process.

powerfail Execute the process associated with this entry only when *init* receives a power fail signal [SIGPWR, see signal(2)].

powerwait Execute the process associated with this entry only when *init* receives a power fail signal (SIGPWR) and wait until it terminates before continuing any processing of *inittab*.

off If the process associated with this entry is currently running, send the warning signal (SIGTERM) and wait 20 seconds before forcibly terminating the process via the kill signal (SIGKILL). If the process is nonexistent, ignore the entry.

ondemand This instruction is really a synonym for the respawn action. It is functionally identical to respawn but is given a different keyword in order to divorce its association with *run-levels*. This is used only with the a, b or c values described in the *rstate* field.

initidefault An entry with this action is only scanned when init initially invoked. Init uses this entry, if it exists, to determine which run-level to enter initially. It does this by taking the highest run-level specified in the rstate field and using that as its initial state. If the rstate field is empty, this is interpreted as 0123456 and so init will enter run-level 6. Additionally, if init does not find an initdefault entry in /etc/inittab, then it will request an initial run-level from the user at reboot time.

sysinit Entries of this type are executed before *init* tries to access the console (i.e., before the Console Login: prompt). It is expected that this entry will be only used to initialize devices on which *init* might try to ask the *run-level* question. These entries are executed and waited for before continuing.

process This is a sh command to be executed. The entire process field is prefixed with exec and passed to a forked sh as sh -c 'exec command'. For this reason, any legal sh syntax can appear in the process field. Comments can be inserted with the; #comment syntax.

NOTES

Strictly speaking, except for comments in the *process* field, there is no comment convention for inittab files. Note in particular that a leading # in itself does not cause a line to be treated as a comment. However, lines not in the

id:rstate:action:process format will be ignored by init.

April 1990 - 4 - Version 5.0

inode - format of an Extent File System inode

SYNOPSIS

```
#include <sys/param.h>
#include <sys/inode.h>
```

DESCRIPTION

An *inode* is the volume data structure used by a file system to implement the abstraction of a file. (This is not to be confused with the *in-core inode* used by the operating system to manage files in use.)

An *inode* contains the type (e.g., plain file, directory, symbolic link, or device file) of the file; its owner, group and public access permissions; the owner and group id numbers; its size in bytes; the number of links (directory references) to the file; and the times of last access and last modification to the file. In addition, there is a file system type-dependent representation of the list of data blocks claimed by the file.

An inode under the Extent File System has the following structure.

```
#define EFS_DIRECTEXTENTS 12
```

```
* Extent based file system inode as it appears on disk.
* The efs inode is 128 bytes long.
*/
        efs_dinode {
struct
        ushort di_mode;
                                  /* type and access permissions */
                                  /* number of links */
        short
                 di nlink;
                                  /* owner's user id number */
        ushort di_uid;
        ushort di_gid;
                                  /* group's group id number */
                                  /* number of bytes in file */
                 di_size;
        off_t
                                  /* time of last access (to contents) */
        time_t di_atime;
                                  /* of last modification (of contents) */
        time_t di_mtime;
        time_t di_ctime;
                                  /* of last modification to inode */
        long
                 di gen;
                                  /* generation number */
        short
                 di numextents; /* # of extents */
                                  /* UNUSED */
        short
                 di_unused;
        union {
                         di extents[EFS DIRECTEXTENTS];
                 extent
                         di_dev; /* device for IFCHR/IFBLK */
                 dev_t
        } di_u;
};
```

April 1990 - 1 - Version 5.0

The types ushort, off_t, time_t, and dev_t are defined in types(5). The extent type is defined as follows:

```
typedef struct extent {
    unsigned int
    ex_magic:8, /* magic #, must be 0 */
    ex_bn:24, /* bb # on volume */
    ex_length:8, /* length of this extent in bb's */
    ex_offset:24; /* logical file offset in bb's */
} extent;
```

di_mode contains the type of the file (plain file, directory, etc), and its read, write, and execute permissions for the file's owner, group, and public. di_nlink contains the number of links to the inode. Correctly formed directories have a minimum of two links: a link in the directory's parent and the '.' link in the directory itself. Additional links may be caused by '..' links from subdirectories. di_uid and di_gid contain the user id and group id of the file (used to determine which set of access permissions apply: owner, group, or public). di size contains the length of the file in bytes.

di_atime is the time of last access to the file's contents. di_mtime is the time of last modification of the file's contents. di_ctime is the time of last modification of the inode, as opposed to the contents of the file it represents. These times are given in seconds since the beginning of 1970 GMT.

di_gen is the inode generation number used to sequence instantiations of the inode.

An extent descriptor maps a logical segment of a file to to a physical segment (i.e., extent) on the volume. The physical segment is characterized by a starting address and a length, both in basic blocks (of 512 bytes) and a logical file offset, also in basic blocks.

di_numextents is the number of extents claimed by the file. If less than or equal to EFS_DIRECTEXTENTS then the extent descriptors appear directly in the inode as di_u.di_extents[0 .. di_numextents-1]. When the number of extents exceeds this range, then di_u.di_extents[0 .. di_u.di_extents[0].ex_offset-1] are indirect extents that map blocks holding extent information. There are at most EFS_DIRECTEXTENTS indirect extents.

If the inode is a block or character special inode, di_u.di_numexents is 0, and di u.di dev contains a number identifying the device.

ldfcn - common object file access routines

SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>

DESCRIPTION

The common object file access routines are a collection of functions for reading an object file that is in common object file form. Although the calling program must know the detailed structure of the parts of the object file that it processes, the routines effectively insulate the calling program from knowledge of the overall structure of the object file.

The interface between the calling program and the object file access routines is based on the defined type LDFILE (defined as struct ldfile), which is declared in the header file <ld>cldfcn.h>. Primarily, this structure provides uniform access to simple object files and object files that are members of an archive file.

The function ldopen(3X) allocates and initializes the LDFILE structure, reads in the symbol table header, if present, and returns a pointer to the structure to the calling program. The fields of the LDFILE structure can be accessed individually through macros defined in < ldfen.h>. The fields contain the following information:

LDFILE *ldptr;

TYPE(ldptr) The file magic number, used to distinguish between

archive members and simple object files.

IOPTR(ldptr) The file pointer returned by fopen(3S) and used by the

standard input/output functions.

OFFSET(ldptr) The file address of the beginning of the object file; if the

object file is a member of an archive file, the offset is

non-zero.

HEADER(ldptr) The file header structure of the object file.

SYMHEADER(ldptr)

The symbolic header structure for the symbol table associated with the object file.

PFD(ldptr)

The file table associated with the symbol table.

SYMTAB(ldptr)

A pointer to a copy of the symbol table in memory. It's accessed through the pCHDR structure (see <*cmplrs/stsupport.h>*). If no symbol table is present, this field is NULL. NOTE: This macro causes the whole symbol table to be read.

LDSWAP(ldptr)

If the header and symbol table structures are swapped within the object file and all access requires using libsex, this field is set to true. **NOTE:** If you use *libmld.a* routines, all structures, except the optional header and auxiliaries, are swapped.

The object file access functions can be divided into five categories:

(1) functions that open or close an object file

ldopen(3X) and ldaopen
open a common object file
ldclose(3X) and ldaclose
close a common object file

(2) functions that return header or symbol table information

ldahread(3X)

read the archive header of a member of an archive file

Idfhread(3X)

read the file header of a common object file

ldshread(3X) and ldnshread

read a section header of a common object file

ldtbread(3X)

read a symbol table entry of a common object file

ldgetname(3X)

retrieve a symbol name from a symbol table entry or from the string table

ldgetaux(3X)

retrieve a pointer into the aux table for the specified ldptr

ldgetsymstr(3X)

create a type string (for example, C declarations) for the specified symbol

ldgetpd(3X)

retrieve a procedure descriptor

ldgetrfd(3X)

retrieve a relative file table entry

(3) functions that position an object file at (seek to) the start of the section, relocation, or line number information for a particular section

ldohseek(3X)

seek to the optional file header of a common object file

ldsseek(3X) and ldnsseek

seek to a section of a common object file

ldrseek (3X) and ldnrseek

seek to the relocation information for a section of a common object file

ldlseek(3X) and ldnlseek

seek to the line number information for a section of a common object file

ldtbseek(3X)

seek to the symbol table of a common object file

(4) miscellaneous functions

ldtbindex(3X)

return the index of a particular common object file symbol table entry

ranhashinit(3X)

initialize the tables and constants so that the archive hash and lookup routines can work

ranhash(3X)

give a string return the hash index for it

ranlookup(3X)

return an archive hash bucket that is empty or matches the string argument

disassembler(3X)

print MIPS assembly instructions

ldreadst(3X)

cause section of the the symbol table to be read

These functions are described in detail in the manual pages identified for each function.

Ldopen and ldaopen both return pointers to a LDFILE structure.

MACROS

Additional access to an object file is provided through a set of macros defined in < ldfcn.h>. These macros parallel the standard input/output file reading and manipulating functions. They translate a reference of the LDFILE structure into a reference to its file descriptor field.

The following macros are provided:

GETC(ldptr)
FGETC(ldptr)
GETW(ldptr)
UNGETC(c, ldptr)
FGETS(s, n, ldptr)
FREAD((char *) ptr, sizeof (*ptr), nitems, ldptr)
FSEEK(ldptr, offset, ptrname)
FTELL(ldptr)
REWIND(ldptr)
FEOF(ldptr)
FERROR(ldptr)
FILENO(ldptr)
SETBUF(ldptr, buf)
STROFFSET(ldptr)

The STROFFSET macro calculates the address of the local symbol's string table in an object file. See the manual entries for the corresponding standard input/output library functions for details on the use of these macros. (The functions are identified as 3S in Section 3 of this manual.)

The program must be loaded with the object file access routine library libmld.a.

WARNINGS

The macro FSEEK defined in the header file < ldfcn.h> translates into a call to the standard input/output function fseek(3S). FSEEK should not be used to seek from the end of an archive file since the end of an archive file cannot be the same as the end of one of its object file members.

When applied to object files in an archive FSEEK (ldptr,offset,BEGINNING) uses (and FTELL returns) an offset relative to the beginning of an individual object file, not the absolute file locations used by *fseek* (stream,offset,0) (and returned by *ftell*).

limits – file header for implementation-specific constants

SYNOPSIS

#include tinclude <float.h>

DESCRIPTION

The header file <*limits.h>* is a list of *minimum* magnitude limitations imposed by the IRIX operating system. In some cases, the actual values may be greater, and can be obtained at runtime via sysconf() or pathconf() system calls (depending upon the variable desired). In this way a program can use, for example, dynamic memory allocation to utilize greater-thandefault limits. See sysconf(2) and pathconf(2). <*limits.h>* also specifies the sizes of integral types as required by the proposed ANSI C standard.

The header file <float.h> specifies the characteristics of floating types as required by the proposed ANSI C standard. The constants that refer to long doubles (those prefixed by LDBL_) that appear in <float.h> are not specified because long doubles are not implemented.

All values in < limits.h> and < float.h> are specified in decimal.

The file < limits.h > contains:

```
#define ARG_MAX
                           10240
                                                     /* max length of arguments to exec */
#define CHAR_BIT
                           8
                                                     /* # of bits in a "char" */
#define CHAR_MAX
                           255
                                                     /* max integer value of a "char" */
#define CHAR_MIN
                           0
                                                     /* min integer value of a "char" */
#define CHILD_MAX
                           25
                                                     /* max # of processes per user id */
#define CLK_TCK
                           100
                                                     /* # of clock ticks per second */
#define DBL_DIG
                           15
                                                     /* digits of precision of a "double" */
#define DBL_MAX
                           1.797693134862316e+308 /* max decimal value of a "double" */

POSIX additions to *limits.h>*. The POSIX 1003.1 standard requires the following symbols to be defined in *limits.h>*, with the values shown. These define *minimum* values for certain features of the system; hence no POSIX 1003.1 conforming system can provide a more restrictive value. For each of these symbols, there is an analogous symbol defined in *limits.h>*, which reflects the actual implementation, and which are, in most cases, less restrictive.

linenum – line number entries in a MIPS object file

SYNOPSIS

#include <sym.h>

DESCRIPTION

The cc(1), f77(1), pc(1), and pll(1) commands generate an entry in the object file for each source line on which a breakpoint is possible [when any of the commands are invoked with the -g option]. Users can then reference line numbers when using the appropriate software test system (see edge(1) and dbx(1)). The structure of these line number entries is described in the Assembly Language Programmer's Guide.

NOTE

Do not include *linenum.h>*; the structures for dealing with line numbers in *<sym.h>* supercede those in *linenum.h>*.

April 1990 - 1 - Version 5.0

login - login configuration file

SYNOPSIS

/etc/config/login.options

DESCRIPTION

login.options is an ASCII file consisting of lines of the form keyword or keyword=value. Keywords can be separated by white-space or placed on separate lines. Keywords that take values must be one word with no white-space between the keyword, equals sign and value. A "#" indicates the beginning of a comment; characters up to the end of the line are ignored.

The following keywords are recognized:

maxtries=value

The number of unsuccessful attempts permitted before ending the session. 0 is "no limit". The default is 5 tries.

disabletime=value

The amount of time in seconds *login* waits before ending the session after maxtries unsuccessful attempts. The default is 20 seconds.

passwdreq

All accounts must have passwords. If the user does not have a password, the user will be forced to choose one before being allowed to login.

lastlog

Inform the user about the last successful login attempt. It shows the date, time and the name of the terminal or remote host from which the previous login attempt occurred.

syslog=value

Record successful and unsuccessful login attempts to syslog(3) if value is all or record unsuccessful attempts only if value is fail.

FILES

/etc/config/login.options

SEE ALSO

getty(1M),

login(1) in the User's Reference Manual.

lvtab - information about logical volumes

DESCRIPTION

The file /etc/lvtab describes the logical volumes used by the local machine. There is an entry in this file for every logical volume which will be used by the machine. It is read by commands that create, install and check the consistency of logical volumes. The system administrator can modify it with a text editor to add new logical volumes or to extend existing ones.

The file consists of entries which have the form:

volume_device_name:[volume_name]:[options]:device_pathnames

For example:

lv0:logical volume test:stripes=3:devs=/dev/dsk/ips0d1s7,\/dev/dsk/ips0d2s7,/dev/dsk/ips0d3s7

Fields are separated by colons, and lines may be continued by the usual backslash convention as illustrated above. A '#' as the first non-white character indicates a comment; blank lines may be present in the file and will be ignored.

The fields in each entry have the following significance:

volume device name

This indicates the names of the special files through which the system will access the logical volume. In the above example, the entry *lv0* implies that the logical volume will be accessed via the device special files /dev/dsk/lv0 and /dev/rdsk/lv0. Note that volume device names are expected to be of the form 'lv' followed by one or 2 digits; this is enforced by the logical volume utilities.

volume name

This is a human-readable identifying name for the logical volume. The logical volume labels on the disks constituting a volume also carry a copy of the volume name, so utilities are able to check that the logical volume on the disks physically present is actually the volume expected by /etc/lvtab.

This field may be null (indicated by a second colon immediately following the one terminating the *volume_device_name* field). This is legal but deprecated, since in this case, no identity check of the logical volume can be done by the utilities.

options Some numerical options concerning the volume may appear. These are specified in the format "option_name=number". There must be no space between the option_name, the '=' sign, and the numerical value given. Options are separated by colons, as with other fields in an entry.

Currently recognized options are:

stripes= step=

The stripes option allows a striped logical volume to be created; the value of the parameter specifies the number of ways the volume storage is striped across its constituent devices. If this option is omitted, the logical volume is unstriped.

The step option is meaningful only for striped volumes (and is ignored otherwise); it specifies the granularity with which the storage is to be round-robin distributed over the constituent devices. If this option is omitted, the default is a step of the device tracksize; this is generally a good value so the step option is not normally needed.

device pathnames

Following any numerical options, there must be a list of the block special file pathnames of the devices constituting the logical volume. This is introduced by the keyword

devs=

The pathnames must be comma-separated.

Each pathname should be the name of the special file for a disk device partition in the /dev/dsk directory. The partition must be one which is legal for use as normal data storage, ie. it must not be one of the dedicated partitions such as the disk volume label, track replacement area etc.

Note that if the volume is striped, some restrictions apply: the number of pathnames must be a multiple of stripes. Further, considering the pathnames as successive groups, each of stripes pathnames, the devices in each group must be all of the same size, and must have the same number of sectors per track.

To obtain best performance from striping, each disk (within every group of 'stripes' disks) should be on a separate controller.

The entries from this file are accessed using the routines in *getlvent* (3), which returns a structure of the following form:

```
struct lytabent
                     {
                                *devname;
                                                     /* volume device name */
          char
          char
                                *volname;
                                                     /* volume name (human-readable) */
          unsigned stripe;
                                          /* number of ways striped */
          unsigned gran;
                                          /* granularity of striping */
                                          /* number of constituent devices */
          unsigned ndevs;
                                                     /* not currently used. */
          int
                                mindex;
                                                     /* pathnames of constituent devices */
          char
                                *pathnames[1];
};
```

This structure is defined in the <1vtab.h> include file.

master - master configuration database

DESCRIPTION

The *master* configuration database is a collection of files. Each file contains configuration information for a device or module that may be included in the system. A file is named with the module name to which it applies. This collection of files is maintained in a directory called /usr/sysgen/master.d. Each individual file has an identical format. For convenience, this collection of files will be referred to as the *master* file, as though it was a single file. This will allow a reference to the *master* file to be understood to mean the *individual file* in the master.d directory that corresponds to the name of a device or module. The file is used by the *lboot*(1M) program to obtain device information to generate the device driver and configurable module files. *master* consists of two parts; they are separated by a line with a dollar sign (\$) in column 1. Part 1 contains device information for both hardware and software devices, and loadable modules. Part 2 contains parameter declarations. Any line with an asterisk (*) in column 1 is treated as a comment.

Part 1, Description

Field 1:

Hardwarc devices, software drivers and loadable modules are defined with a line containing the following information. Field 1 must begin in the left most position on the line. Fields are scparated by white space (tab or blank).

element o	characteristics:
0	specify only once
r	required device
b	block device
c	character device
t	initialize cdevsw[].d_ttys
j	file system
S	software driver
f	STREAMS driver
m	STREAMS module
X	not a driver; a loadable module
k	kernel module
n	driver is fully semaphored for multi-
	processor operation; the n, p and l
	directives are ignored on single-
	processor systems

	p driver is not semaphored and should run on only one processor
	q driver is not semaphored and should
	run on network processor
Field 2:	handler prefix (14 chars. maximum)
Field 3:	software driver external major number; "-" if not a software driver, or to be assigned during execution
	of lboot(1M)
Field 4:	number of sub-devices per device; "-" if none
Field 5:	dependency list (optional); this is a comma separated list of other drivers or modules that must be present in the configuration if this module is to be included

For each module, two classes of information are required by *lboot* (1M): external routine references and variable definitions. Routine lines begin with white space and immediately follow the initial module specification line. These lines are free form, thus they may be continued arbitrarily between non-blank tokens as long as the first character of a line is white space. Variable definition lines begin after a line that contains a '\$' in column one. Variable definitions follow C language conventions, with slight modifications.

Part 1, Routine Reference Lines

If the UNIX system kernel or other dependent module contains external references to a module, but the module is not configured, then these external references would be undefined. Therefore, the *routine reference* lines are used to provide the information necessary to generate appropriate dummy functions at boot time when the driver is not loaded.

Routine references are defined as follows:

```
Field 1: routine name ()

Field 2: the routine type: one of
{} routine_name(){}

{nulldev}

routine_name(){nulldev();}

{nosys} routine_name(){return nosys();}

{nodev}

routine_name(){return nodev();}

{false} routine_name(){return 0;}

{true} routine_name(){return 1;}
```

Part 2, Variables

Variables may be declared and (optionally) statically initialized on lines after a line whose first character is a dollar sign ('\$'). Variable definitions follow standard C syntax for global declarations, with the following in-line substitutions:

##M	the internal major number assigned to the current module if it is a device driver; zero if this module is not a device driver
	not a device driver
##E	the external major number assigned to the current
	module; either explicitly defined by the current
	master file entry, or assigned by lboot(1M)
##C	number of controllers present; this number is deter-
	mined dynamically by lboot(1M) for hardware dev-
	ices, or by the number provided in the system file
	for non-hardware drivers or modules
##D	number of devices per controller taken directly
	from the current master file entry

EXAMPLES

A sample *master* file for a shared memory module would be named "shm". The module is an optional loadable software module that can only be specified once. The module prefix is shm, and it has no major number associated with it. In addition, another module named "*ipc*" is necessary for the correct operation of this module.

* FLAG PREFIX SOFT #DEV DEPENDENCIES

```
#define SHMMAX 131072
#define SHMMIN 1
#define SHMMNI 100
#define SHMSEG 6
#define SHMALL 512

struct shmid_ds shmem[SHMMNI];
struct shminfo shminfo = {
    SHMMAX,
    SHMMIN,
    SHMMNI,
    SHMSEG,
    SHMALL,
};
```

This master file will cause routines named shmsys, shmexec, etc., to be generated by the boot program if the shm driver is not loaded, and there is a reference to this routine from any other module loaded. When the driver is loaded, the structure array shmem will be allocated, and the structure shminfo will be allocated and initialized as specified.

A sample *master* file for a VME disk driver would be named "dkip" The driver is a block and a character device, the driver prefix is dkip, and the external major number is 4. The VME interrupt priority level and vector numbers are declared in the system file *lusr/sysgen/system* (see lboot(1M)).

```
bc dkip 4 - - io

$$$

/* disk driver variable tables */
#include "sys/dvh.h"

#include "sys/dkipreg.h"

#include "sys/elog.h"

struct iotime dkipiotime[##C][DKIPUPC]; /* io statistics */
struct iobuf dkipctab[##C]; /* controller queues */
```

* FLAG PREFIX SOFT #DEV DEPENDENCIES

struct iobuf dkiputab[##C][DKIPUPC];

int dkipmajor = ##E;

This *master* file will cause entries in the block and character device switch tables to be generated, if this module is loaded. Since this is a hardware device (implied by the block and character flags), VME interrupt structures

/* drive queues */
/* external major # */

April 1990 - 4 - Version 5.0

will be generated, also, by the boot program. The declared arrays will all be sized to the number of controllers present, which is determined by the boot program, based on information in the system file /usr/sysgen/system.

April 1990 - 1 - Version 5.0

mtab - mounted file system table

DESCRIPTION

Mtab resides in the /etc directory, and contains a table of filesystems currently mounted by the mount command. Umount removes entries from this file.

The file contains a line of information for each mounted filesystem, structurally identical to the contents of *letclfstab*, described in *fstab*(4). There are a number of lines of the form:

fsname dir type opts freq passno

For example:

/dev/root / efs rw 00

The file is accessed by programs using *getmntent*(3), and by the system administrator using a text editor.

FILES

/etc/mtab

mount(1M), fstab(4) getmntent(3) if the NFS option is installed.

networks - network name data base

DESCRIPTION

The /etc/networks file contains information regarding the known networks which comprise the DARPA Internet. For each network a single line should be present with the following information:

official network name network number aliases

Items are separated by any number of blanks and/or tab characters. A "#" indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. This file is normally created from the official network data base maintained at the Network Information Control Center (NIC), though local changes may be required to bring it up to date regarding unofficial aliases and/or unknown networks.

Network number may be specified in the conventional "." notation using the *inet_network()* routine from the Internet address manipulation library, *inet(3N)*. Network names may contain any printable character other than a field delimiter, newline, or comment character.

YELLOW PAGES

If the NFS option is installed and Yellow Pages is running, the getnetent(3N) library routines do not access this file.

FILES

/etc/networks

SEE ALSO

getnetent(3N)

BUGS

A name server should be used instead of a static file. A binary indexed file format should be available for fast access.

passwd - password file

DESCRIPTION

The /etc/passwd file contains the following information for each user:

name User's login name — contains no upper case characters and must not be greater than eight characters long.

password Encrypted password and optional password aging information

numerical user ID

This is the user's ID in the system and it must be unique.

numerical group ID

This is the number of the group that the user belongs to.

user's real name

In some versions of UNIX, this field also contains the user's office, extension, home phone, and so on. For historical reasons this field is called the GECOS field.

initial working directory

The directory that the user is positioned in when they log in — this is known as the 'home' directory.

shell program to use as Shell when the user logs in.

An entry beginning with # is ignored. The user's real name field may contain '&', meaning insert the login name.

The password file is an ASCII file. Each field within each user's entry is separated from the next by a colon. Each user is separated from the next by a new-line. If the password field is null, no password is demanded; if the Shell field is null, /bin/sh is used.

Password aging is effected for a particular user if his encrypted password is followed by a comma and a non-null string of characters from a 64-character alphabet (.,/,0-9, A-Z, a-z). The first character of the age, M say, denotes the maximum number of weeks for which a password is valid. A user who attempts to login after his password has expired will be forced to change his password. The next character, m say, denotes the minimum period in weeks which must expire before the password may be changed. If the second character is omitted, zero week is the default minimum. M and m have numerical values in the range 0-63 that correspond to the 64-character alphabet shown above (i.e., l = 1 week; z = 63 weeks). If m = M = 0 (derived from the string . or ..) the user will be forced to change his password the next time he logs in (and the "age" will disappear from his entry in the password file). If m > M (signified, e.g., by the string l) only the superuser will be able to change the password.

The password file resides in the /etc directory. Because of the encrypted passwords, it has general read permission and can be used, for example, to map numerical user ID's to names.

The passmgmt command can be used to update information in the \(\text{/passwd} \) file. Appropriate precautions must be taken to lock the \(\text{/passwd} \) file against simultaneous changes if it is to be edited with a text editor.

YELLOW PAGES

If the NFS option is installed, the *passwd* file can also have a line beginning with a plus (+), which means to incorporate entries from the Yellow Pages. There are three styles of + entries: all by itself, + means to insert the entire contents of the Yellow Pages password file at that point; +name means to insert the entry (if any) for *name* from the Yellow Pages at that point; +@name means to insert the entries for all members of the network group name at that point. If a + entry has a non-null password, directory, GECOS, or shell field, they will override what is contained in the Yellow Pages. The numerical user ID and group ID fields cannot be overridden.

Here is a sample /etc/passwd file:

root:q.mJzTnu8icF.:0:10:superuser:/:/bin/cshbill:6k/7KCFRPNVXg,z/:508:10:Bill The Cat:/usr2/bill:/bin/csh

- +@documentation:no-login:
- +:::Guest

In this example, there are specific entrics for users *root* and *bill*, in case the Yellow Pages are not functioning. The user *bill* will have 63 weeks of maximum password aging and 1 week of minimum password aging. The user *john* will have his password entry in the Yellow Pages incorporated without change; anyone in the netgroup *documentation* will have their password field disabled, and anyone else will be able to log in with their usual password, shell, and home directory, but with a GECOS field of *Guest*.

pnch - file format for card images

DESCRIPTION

The PNCH format is a convenient representation for files consisting of card images in an arbitrary code.

A PNCH file is a simple concatenation of card records. A card record consists of a single control byte followed by a variable number of data bytes. The control byte specifies the number (which must lie in the range 0-80) of data bytes that follow. The data bytes are 8-bit codes that constitute the card image. If there are fewer than 80 data bytes, it is understood that the remainder of the card image consists of trailing blanks.

printeap – printer eapability data base

SYNOPSIS

/ete/printeap

DESCRIPTION

Printcap is a simplified version of the *termcap* (4) data base used to describe line printers. The spooling system accesses the *printcap* file every time it is used, allowing dynamic addition and deletion of printers. Each entry in the data base is used to describe one printer. This data base may not be substituted for, as is possible for *termcap*, because it may allow accounting to be bypassed.

The default printer is normally lp, though the environment variable PRINTER may be used to override this. Each spooling utility supports an option, -Pprinter, to allow explicit naming of a destination printer.

Refer to the 4.3BSD Line Printer Spooler Manual for a complete discussion on how setup the database for a given printer.

CAPABILITIES

Refer to termcap(4) for a description of the file layout.

Name	Type	Default	Description	
af	str	NULL	name of accounting file	
br	num	none	if lp is a tty, sct the baud rate (ioctl call)	
cf	str	NULL	cifplot data filter	
df	str	NULL	tex data filter (DVI format)	
fc	num	0	if lp is a tty, clear flag bits (see compatibility notes)	
ff	str	"\f",	string to send for a form feed	
fo	bool	false	print a form feed when device is opened	
fs	num	0	like 'fc' but set bits (see compatibility notes)	
gf	str	NULL	graph data filter (plot (3X) format)	
hl	bool	false	print the burst header page last	
ic	bool	false	driver supports (non standard) ioetl to indent printout	
if	str	NULL	name of text filter which does accounting	
lf	str	"'/dcv/console"	error logging file name	
lo	str	"lock"	name of lock file	
lp	str	''/dev/lp''	device name to open for output	

Name	Type	Default	Description	
mx	num	1000	maximum file size in BUFSIZ bloeks, zero unlimited	
nd	str	NULL	next directory for list of queues (unimplemented	
nf	str	NULL	ditroff data filter (device independent troff)	
of	str	NULL	name of output filtering program	
pc	num	200	price per foot or page in hundredths of cents	
pl	num	66	page length (in lines)	
pw	num	132	page width (in characters)	
px	num	0	page width in pixels (horizontal)	
ру	num	0	page length in pixels (vertical)	
rf	str	NULL	filter for printing FORTRAN style text files	
rg	str	NULL	restrieted group. Only members of group allowed aeeess	
rm	str	NULL	machine name for remote printer	
rp	str	"lp"	remote printer name argument	
rs	bool	false	restrict remote users to those with local accounts	
rw	bool	false	open the printer device for reading and writing	
sb	bool	false	short banner (one line only)	
se	bool	false	suppress multiple eopies	
sd	str	"/usr/spool/lpd"	spool directory	
sf	bool	false	suppress form feeds	
sh	bool	false	suppress printing of burst page header	
st	str	"status"	status file name	
tf	str	NULL	troff data filter (eat phototypesetter)	
tr	str	NULL	trailer string to print when queue empties	
vf	str	NULL	raster image filter	
xe	num	0	if lp is a tty, clear local mode bits (tty (4))	
XS	num	0	like 'xe' but set bits	

If the local line printer driver supports indentation, the daemon must understand how to invoke it.

FILTERS

The lpd(1M) daemon creates a pipeline of *filters* to process files for various printer types. The filters selected depend on the flags passed to lpr(1). The pipeline set up is:

pr l if	regular text + $pr(1)$
if	regular text
cf	cifplot
df	DVI (tex)
	if cf

-g	gf	plot(3)
-n	nf	ditroff
$-\mathbf{f}$	rf	Fortran
−t	ιf	troff
-v	vf	raster image

The if filter is invoked with arguments:

The -c flag is passed only if the -l flag (pass control characters literally) is specified to *lpr*. Width and *length* specify the page width and length (from **pw** and **pl** respectively) in characters. The -n and -h parameters specify the login name and host name of the owner of the job respectively. Acct-file is passed from the af printcap entry.

If no if is specified, of is used instead, with the distinction that of is opened only once, while if is opened for every individual job. Thus, if is better suited to performing accounting. The of is only given the width and length flags.

All other filters are called as:

where width and length are represented in pixels, specified by the px and py entries respectively.

All filters take *stdin* as the file, *stdout* as the printer, may log either to *stderr* or using *syslog*(3), and must not ignore SIGINT.

LOGGING

Error messages generated by the line printer programs themselves (that is, the lp^* programs) are logged by syslog(3) using the LPR facility. Messages printed on stderr of one of the filters are sent to the corresponding If file. The filters may, of course, use syslog themselves.

Error messages sent to the console have a carriage return and a line feed appended to them, rather than just a line feed.

COMPATIBILITY NOTES

In an attempt to provide compatibility with existing BSD printcap entries, the SGI version of the *lpd* spooler emulates the output bits in the BSD tty flag word (defined in the BSD include file <sgtty.h>) via IRIX termio.

profile - setting up an environment at login time

SYNOPSIS

/etc/profile \$HOME/.profile

DESCRIPTION

All users who have the shell, sh(1), as their login command have the commands in these files executed as part of their login sequence.

letclprofile allows the system administrator to perform services for the entire user community. Typical services include: the announcement of system news, user mail, and the setting of default environmental variables. It is not unusual for *letclprofile* to execute special actions for the **root** login or the su(1) command.

The file \$HOME!.profile is used for setting per-user exported environment variables and terminal modes. The following example is typical (except for the comments):

```
# Set the file creation mask to prohibit

# others from reading my files.
umask 027

# Add my own /bin directory to the shell search sequence.
PATH=$PATH:$HOME/bin

# Set terminal type
eval 'tset -S -Q'

# Set the interrupt character to control-c.
stty intr 'c

# List directories in columns if standard out is a terminal.
ls() { if [-t]; then /bin/ls -C $*; else /bin/ls $*; fi }
```

FILES

```
/etc/TIMEZONE timezone environment
$HOME/.profile user-specific environment
/etc/profile system-wide environment
```

SEE ALSO

```
terminfo(4), timezone(4), environ(5), term(5).
env(1), login(1), mail(1), sh(1), stty(1), tset(1), tput(1) in the User's Reference Manual.
su(1M) in the System Administrator's Reference Manual.
User's Guide.
Chapter 9 in the Programmer's Guide.
```

NOTES

Care must be taken in providing system-wide services in /etc/profile. Personal .profile files are better for serving all but the most global needs.

proto – prototype job file for at

SYNOPSIS

/usr/lib/cron/.proto

/usr/lib/cron/.proto.queue

DESCRIPTION

When a job is submitted to at(1) or batch(1), the job is constructed as a shell script. First, a prologue is constructed, consisting of:

• A header whether the job is an *at* job or a *batch* job (actually, *at* jobs submitted to all queues other than queue a, not just to the batch queue b, are listed as *batch* jobs); the header will be

: at job

for an at job, and

: batch job

for a batch job.

- A set of Bourne shell commands to make the environment (see environ(5)) for the at job the same as the current environment;
- A command to run the user's shell (as specified by the SHELL environment variable) with the rest of the job file as input.

At then reads a "prototype file," and constructs the rest of the job file from it.

Text from the prototype file is copied to the job file, except for special "variables" that are replaced by other text:

\$d is replaced by the current working directory

\$1 is replaced by the current file size limit (see *ulimit*(2))

m is replaced by the current umask (see *umask*(2))

st is replaced by the time at which the job should be run, expressed as seconds since January 1, 1970, 00:00 Greenwich Mean Time, preceded by a colon

\$< is replaced by text read by at from the standard input (that is, the commands provided to at to be run in the job)

If the job is submitted in queue queue, at uses the file /usr/lib/cron/.proto.queue as the prototype file if it exists, otherwise it will use the file /usr/lib/cron/.proto.

EXAMPLES

The standard .proto file supplied is:

```
#ident "@(#)adm:.proto 1.2"
cd $d
ulimit $l
umask $m
$<
```

which causes commands to change the current directory in the job to the current directory at the time at was run, to change the file size limit in the job to the file size limit at the time at was run, and to change the umask in the job to the umask at the time at was run, to be inserted before the commands in the job.

BUGS

A name server should be used instead of a static file.

queuedefs - at/batch/cron queue description file

SYNOPSIS

/usr/lib/cron/queuedefs

DESCRIPTION

The *queuedefs* file describes the characteristics of the queues managed by *cron*(1M). Each non-comment line in this file describes one queue. The format of the lines are as follows:

q.[njobj][nicen][nwaitw]

The fields in this line are:

The name of the queue. a is the default queue for jobs started by at(1); b is the default queue for jobs started by batch(1); c is the default queue for jobs run from a crontab file.

njob The maximum number of jobs that can be run simultaneously in that queue; if more than njob jobs are ready to run, only the first njob jobs will be run, and the others will be run as jobs that are currently running terminate. The default value is 100.

nice The nice(1) value to give to all jobs in that queue that are not run with a user ID of super-user. The default value is 2.

nwait The number of seconds to wait before rescheduling a job that was deferred because more than njob jobs were running in that job's queue, or because more than 25 jobs were running in all the queues. The default value is 60.

Lines beginning with # are comments, and are ignored.

EXAMPLE

a.4j1n b.2j2n90w

This file specifies that the a queue, for *at* jobs, can have up to 4 jobs running simultaneously; those jobs will be run with a *nice* value of 1. As no *nwait* value was given, if a job cannot be run because too many other jobs are running *cron* will wait 60 seconds before trying again to run it. The **b** queue, for *batch* jobs, can have up to 2 jobs running simultaneously; those jobs will be run with a *nice* value of 2. If a job cannot be run because too many other jobs are running, *cron* will wait 90 seconds before trying again to run it. All other queues can have up to 100 jobs running simultaneously; they will be run with a *nice* value of 2, and if a job cannot be run because

too many other jobs are running cron will wait 60 seconds before trying again to run it.

rcsfile - format of RCS file

DESCRIPTION

An RCS file is an ASCII file. Its contents are described by the grammar below. The text is free format, i.e., spaces, tabs and new lines have no significance except in strings. Strings are enclosed by '@'. If a string contains a '@', it must be doubled.

The meta syntax uses the following conventions: 'l' (bar) separates alternatives; '{' and '}' enclose optional phrases; '{' and '}*' enclose phrases that may be repeated zero or more times; '{' and '}+' enclose phrases that must appear at least once and may be repeated; '<' and '>' enclose nonterminals.

<rcstext></rcstext>	::=	<admin> {<delta>}* <desc> {<deltatext>}*</deltatext></desc></delta></admin>	
<admin></admin>	::=	head access symbols locks comment	{ <num>}; {<id>}*; {<id>:<num>}*; {<id>:<num>}*; {<id>:<num>}*;</num></id></num></id></num></id></id></num>
<delta></delta>	::=	<num> date author state branches next</num>	<num>; <id>; <id>; <id>); {<id>}; {<num>}*; {<num>};</num></num></id></id></id></id></num>
<desc></desc>	::=	desc	<string></string>
<deltatext></deltatext>	::=	<num> log text</num>	<string> <string></string></string>
<num></num>	::=	{ <digit>{.}}+</digit>	
<digit></digit>	::=	011119	
<id>></id>	::=	<letter>{<idchar>}*</idchar></letter>	
<letter></letter>	::=	AlBlIZlalblIz	
<idchar></idchar>	::=	Any printing ASCII character except space, tab, carriage return, new line, and <special>.</special>	

<special> ::= ;1:1,1@

<string> ::= @{any ASCII character, with '@' doubled}*@

Identifiers are case sensitive. Keywords are in lower case only. The sets of keywords and identifiers may overlap.

The <delta> nodes form a tree. All nodes whose numbers consist of a single pair (e.g., 2.3, 2.1, 1.3, etc.) are on the "trunk", and are linked through the "next" field in order of decreasing numbers. The "head" field in the <admin> node points to the head of that sequence (i.e., contains the highest pair).

All <delta> nodes whose numbers consist of 2n fields (n≥2) (e.g., 3.1.1.1, 2.1.2.2, etc.) are linked as follows. All nodes whose first (2n)-1 number fields are identical are linked through the "next" field in order of increasing numbers. For each such sequence, the <delta> node whose number is identical to the first 2(n-1) number fields of the deltas on that sequence is called the branchpoint. The "branches" field of a node contains a list of the numbers of the first nodes of all sequences for which it is a branchpoint. This list is ordered in increasing numbers.

reloc - relocation information for a common object file

SYNOPSIS

#include <reloc.h>

DESCRIPTION

Object files have one relocation entry for each relocatable reference in the text or data. If relocation information is present, it will be in the following format.

```
struct reloc
                                     /* (virtual) address of
        long
                    r_vaddr;
                                       reference */
        unsigned
                                     /* index into symbol
                    r_symndx:24,
                                       table */
                    r_reserved:3,
                    r_type:4,
                                     /* relocation type */
                    r_extern:1;
                                     /* if 1 symndx is an index
                                       into the extern symb tab
                                       else symndx is a
                                       section # */
};
/* Relocation types */
#define R_ABS
                       0
#define R_REFHALF
                        1
#define R_REFWORD
                       2
#define R_JMPADDR
                        3
                        4
#define R_REFHI
#define R_REFLO
                       5
#define R_GPREL
                       6
#define R_LITERAL
                       7
/* Section numbers */
#define R_SN_NULL
                       0
#define R_SN_TEXT
                       1
#define R_SN_RDATA
                       2
#define R_SN_DATA
                       3
#define R_SN_SDATA
                       4
                       5
#define R_SN_SBSS
#define R_SN_BSS
                       6
#define R_SN_INIT
                       7
#define R_SN_LIT8
                       8
```

#define R_SN_LIT4 9

The link editor reads each input section and performs relocation. The relocation entries direct how references found within the input section are treated.

If r_extern is zero, then the reference is a local relocation entry and the r_symndex is a section number (R_SN_*). For these entries, the starting address for the section referenced by the section number is used in place of an external symbol table entry's value. The assembler and loader always use local relocation entries if the item to be relocated is defined in the object file.

For every external relocation (except **R_ABS**), a signed constant is added to the symbols vierual address that the relocation entry refers to. This constant is assembled at the address being relocated.

R_ABS	The reference is absolute	e and no relocation is neces-
-------	---------------------------	-------------------------------

sary. The entry will be ignored.

R_REFHALF A 16-bit reference to the symbol's virtual address.

R_REFWORD A 32-bit reference to the symbol's virtual address.

R_JMPADDR A 26-bit jump instruction reference to the symbol's

virtual address.

R_REFHI A reference to the high 16 bits of the the symbol's 16

bits of the symbol's virtual address. The next relocation entry must be the corresponding R_REFLO entry so the proper value of the constant to be added to the symbol's virtual address can be reconstructed.

R_REFLO A reference to the low 16-bits of the symbol's virtual

address.

R GPREL A 16-bit offset to the symbol's virtual address from

the global pointer register.

R_LITERAL A 16-bit offset to the literal's virtual address from the

global pointer register.

Relocation entries are generated automatically by the assembler and automatically used by the link editor. Link editor options exist for both preserving and removing the relocation entries from object files.

The number of relocation entries for a section is found in the <u>s_nreloc</u> field of the section header. This field is a C language short and can overflow with large objects. If this field overflows, the section header <u>s_flags</u> field has the S NRELOC OVFL bit set. In this case, the true number of

relocation entries is found in the r_vaddr field of the first relocation entry for that section. That relocation entry has a type of R_ABS so it is ignored when the relocation takes place.

resolver - host-address resolver configuration file

SYNOPSIS

/usr/etc/resolv.conf

DESCRIPTION

This file controls the behavior of *gethostbyname*(3N), *gethostbyaddr*(3N) and the *resolver*(3N) routines in the C library. It is read by these routines the first time they are invoked by a process.

The file is designed to be human readable and contains a list of keywords with values that provide various types of resolver information. The keyword and value must appear on a single line, and the keyword (e.g., nameserver) must start the line. The value follows the keyword, separated by white space.

This file is not necessary if there is a name server running on the local machine and the host name contains the domain name. It is necessary, however, if the system administrator wants to override the default ordering of the host lookup services.

The following configuration option applies to *gethostbyname*(3N) and *gethostbyaddr*(3N):

hostresorder

A list specifying the ordering of host lookup services used by gethostbyname (3N) and gethostbyaddr (3N). The recognized services and their keywords are Yellow Pages ("yp"), BIND ("bind") and /etc/hosts ("local"). The keywords are separated by white space or a slash (/). Normally, if a service cannot find the answer or is not running, the next service in the list is queried. The slash separator indicates the previous service in the list is authoritative: even if it cannot find the answer, the search is terminated. For example,

hostresorder bind local

specifies that BIND is checked first (bypassing YP) and if no answer is found, the file /etc/hosts is then checked. At least one service keyword must be listed. The default is "yp / bind / local", i.e., YP and BIND have authoritative information if they are available. A user may override the ordering specified by hostresorder with the environment variable HOSTRESORDER set to a string containing the service keywords.

The following options are used by the Internet Domain Name System resolver routines only:

nameserver

Internet address (in dot notation) of a name server that the resolver should query. Up to 3 of these lines may be specified; the resolver library queries them in the order listed. If no nameserver entries are present, the default is to use the name server on the local machine. (The algorithm used is to try a name server, and if the query times out, try the next, until out of name servers, then repeat trying all the name servers until a maximum number of retries are made). When specifying a nameserver entry for the local machine, use the address 0 instead of the "localhost" address of 127.1.

domain Local domain name. Most queries for names within this domain can use short names relative to the local domain. If no domain entry is present, the domain is determined from the local host name returned by *gethostname* (2); the domain part is taken to be everything after the first '.'. Finally, if the host name does not contain a domain part, the root domain is assumed.

search list for host-name lookup. The search list is normally determined from the local domain name; by default, it begins with the local domain name, then successive parent domains that have at least two components in their names. This may be changed by listing the desired domain search path following the search keyword with spaces or tabs separating the names. Most resolver queries will be attempted using each component of the search path in turn until a match is found. Note that this process may be slow and will generate a lot of network traffic if the servers for the listed domains are not local, and that queries will time out if no server is available for one of the domains.

The search list is currently limited to six domains with a total of 256 characters. The first item in the list becomes the default domain name; the remaining items are the other domains to search after the default one.

The domain and search keywords are mutually exclusive. If more than one instance of these keywords is present, the last instance will override. These keywords are ignored if the environment variable LOCALDOMAIN is set.

NOTE

The hostresorder keyword is specific to IRIX.

FILES

/usr/etc/resolv.conf

ENVIRONMENT

HOSTRESORDER overrides hostresorder

LOCALDOMAIN overrides domain and search

rhosts - list of trusted hosts and users

DESCRIPTION

Each user may have a *.rhosts* file in his home directory. This file contains a list of users on other hosts in the network that are trusted in the following sense: when making requests to access the user's system with rcp(1C), rdist(1C), rlogin(1C), or rsh(1C), they are allowed to assume the user's identity without specifying a password. In other words, the remote user has exactly the same access privileges on the local system that the owner of the *.rhosts* file does and this access is granted without any attempt to verify the remote user's identity by requiring him to enter a password. The incoming request includes the user name that should be used on the local system. The *.rhosts* file owned by that local user acts as a logical extension to the *hosts.equiv*(4) file when deciding whether to grant permission for the incoming rcp(1C), rdist(1C), rlogin(1C), or rsh(1C) request.

The .rhosts file has the same format as the hosts.equiv(4) file.

NOTES

The owner of the .rhosts file must be the super-user (i.e., root) or the user in whose home directory it resides. The contents of the file will be disregarded if it is owned by another user or if its permissions allow anyone who is not the owner to modify the file. Use the chmod(1) command to add the proper protection:

```
chmod go-w .rhosts
```

Special care should be taken in deciding the contents of the file /.rhosts. Any host or user added to this file has the ability to become the superuser on the local system without entering the password. Note that /.rhosts is not required.

rpc - RPC program number data base

SYNOPSIS

/etc/rpc

DESCRIPTION

The *rpc* file contains user readable names that can be used in place of Sun RPC program numbers. Each line has the following information:

```
name of server for the RPC program RPC program number aliases
```

Items are separated by any number of blanks and/or tab characters. A "#" indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.

Here is an excerpt of the /etc/rpc file on IRIX:

```
#
```

```
# rpc 1.10 87/04/10
```

#

portmapper 100000 portmap sunrpc rstatd 100001 rstat rup perfmeter rusersd 100002 rusers

sccsfile - format of SCCS file

DESCRIPTION

An SCCS (Source Code Control System) file is an ASCII file. It consists of six logical parts: the *checksum*, the *delta table* (contains information about each delta), *user names* (contains login names and/or numerical group IDs of users who may add deltas), *flags* (contains definitions of internal keywords), *comments* (contains arbitrary descriptive information about the file), and the *body* (contains the actual text lines intermixed with control lines).

Throughout an SCCS file there are lines which begin with the ASCII SOH (start of heading) character (octal 001). This character is hereafter referred to as *the control character* and will be represented graphically as @. Any line described below which is not depicted as beginning with the control character is prevented from beginning with the control character.

Entries of the form **DDDDD** represent a five-digit string (a number between 00000 and 99999).

Each logical part of an SCCS file is described in detail below.

Checksum

The checksum is the first line of an SCCS file. The form of the line is:

@hDDDDD

The value of the checksum is the sum of all characters, except those of the first line. The @h provides a magic number of (octal) 064001.

Delta table

The delta table consists of a variable number of entries of the form:

```
@s DDDDD/DDDDD/DDDDD
```

- @d <type> <SCCS ID> yr/mo/da hr:mi:se <pgmr> DDDDD DDDDD
- @i DDDDD ...
- @x DDDDD ...
- @g DDDDD ...
- @m <MR number>

@c <comments> ...

. @e

The first line (@s) contains the number of lines inserted/deleted/unchanged, respectively. The second line (@d) contains the type of the delta (currently, normal: D, and removed: R), the SCCS ID of the delta, the date and time of creation of the delta,

the login name corresponding to the real user ID at the time the delta

login name corresponding to the real user ID at the time the delta was created, and the serial numbers of the delta and its predecessor, respectively.

The @i, @x, and @g lines contain the serial numbers of deltas included, excluded, and ignored, respectively. These lines are optional.

The @m lines (optional) each contain one MR number associated with the delta; the @c lines contain comments associated with the delta.

The @e line ends the delta table entry.

User names

The list of login names and/or numerical group IDs of users who may add deltas to the file, separated by new-lines. The lines containing these login names and/or numerical group IDs are surrounded by the bracketing lines @u and @U. An empty list allows anyone to make a delta. Any line starting with a! prohibits the succeeding group or user from making deltas.

Flags

Keywords used internally. [See *admin*(1) for more information on their use.] Each flag line takes the form:

The following flags are defined:

@f f <floor>
@f c <ceiling>

@f d <default-sid>
@f n
@f j
@f l <lock-releases>
@f q <user defined>
@f z <reserved for use in interfaces>

The t flag defines the replacement for the %Y% identification keyword. The v flag controls prompting for MR numbers in addition to comments; if the optional text is present it defines an MR number validity checking program. The i flag controls the warning/error aspect of the "No id keywords" message. When the i flag is not present, this message is only a warning; when the i flag is present, this message will cause a "fatal" error (the file will not be gotten, or the delta will not be made). When the b flag is present the -b keyletter may be used on the get command to cause a branch in the delta tree. The m flag defines the first choice for the replacement text of the %M% identification keyword. The f flag defines the "floor" release; the release below which no deltas may be added. The c flag defines the "ceiling" release; the release above which no deltas may be added. The d flag defines the default SID to be used when none is specified on a get command. The n flag causes delta to insert a "null" delta (a delta that applies no changes) in those releases that are skipped when a delta is made in a new release (e.g., when delta 5.1 is made after delta 2.7, releases 3 and 4 are skipped). The absence of the n flag causes skipped releases to be completely empty. The j flag causes get to allow concurrent edits of the same base SID. The I flag defines a list of releases that are locked against editing (get(1) with the -e keyletter). The q flag defines the replacement for the %Q% identification keyword. The z flag is used in certain specialized interface programs. Comments Arbitrary text is surrounded by the bracketing lines @t and @T. The comments section typically will contain a description of the file's purpose.

Body

The body consists of text lines and control lines. Text lines do not begin with the control character, control lines do. There are three kinds of control lines: *insert*, *delete*, and *end*, represented by:

@I DDDDD @D DDDDD @E DDDDD respectively. The digit string is the serial number corresponding to the delta for the control line.

scnhdr - section header for a MIPS object file

SYNOPSIS

#include <scnhdr.h>

DESCRIPTION

Every MIPS object file has a table of section headers to specify the layout of the data within the file. Each section within an object file has its own header. The C structure appears below:

```
struct scnhdr
{
                                  s_name[8];/* section name */
           char
                                                        /* physical address, aliased s_nlib */
           long
                                  s_paddr;
                                                        /* virtual address */
                                  s_vaddr;
           long
           long
                                  s_size;
                                                        /* section size */
                                  s_scnptr; /* file ptr to raw data for section */
           long
           long
                                                        /* file ptr to relocation */
                                  s_relptr;
                                  s_lnnoptr; /* file ptr to gp table */
           long
           unsigned short
                                  s_nreloc; /* number of relocation entries */
           unsigned short
                                  s nlnno;
                                                        /* number of gp table entries */
           long
                                  s_flags;
                                                        /* flags */
};
```

File pointers are byte offsets into the file; they can be used as the offset in a call to FSEEK [see *ldfcn*(4)]. If a section is initialized, the file contains the actual bytes. An uninitialized section is somewhat different. It has a size, symbols defined in it, and symbols that refer to it. But it can have no relocation entries or data. Consequently, an uninitialized section has no raw data in the object file, and the values for *s_scnptr*, *s_relptr*, and *s_nreloc* are zero.

The entries that refer to line numbers ($s_lnnoptr$ and s_nlnno) are not used for line numbers on MIPS machines. See the header file $\langle sym.h \rangle$ [line-num(4)] for the entries to get to the line number table. The entries that were for line numbers in the section header are used for gp tables on MIPS machines.

The number of relocation entries for a section is found in the *s_nreloc* field of the section header. This field is a C language **short** and can overflow with large objects. If this field overflows, the section header *s_flags* field has the S_NRELOC_OVFL bit set. In this case, the true number of relocation entries is found in the *r_vaddr* field of the first relocation entry for that section. That relocation entry has a type of R_ABS so it is ignored when the relocation takes place.

The gp table gives the section size corresponding to each applicable value of the compiler option -G num (always including 0), sorted by smallest size first. It is pointed to by the s_lnnoptr field in the section header and its number of entries (including the header) is in the s_nlnno field in the section header. This table only needs to exist for the .sdata and .sbss sections. If there is no "small" section then the gp table for it is attached to the coresponding "large" section so the information still gets to the link editor, ld(1). The C union for the gp table appears below.

```
union gp_table
{
           struct {
                                                        /* actual value */
                      long
                                 current_g_value;
                      long
                                 unused;
           header;
           struct {
                      long
                                 g_value;
                                                        /* hypothetical value */
                                                        /* section size corresponding */
                      long
                                 bytes;
                                                        /* to hypothetical value */
           } entry;
};
```

Each gp table has one header structure that contains the actual value of the -G num option used to produce the object file. An entry must exist for every applicable value of the -G num option. The applicable values are all the sizes of the data items in that section.

For .lib sections, the number of shared libraries is in the s_nlib field (an alias to s_paddr). The .lib section is made up of s_nlib descriptions of shared libraries. Each description of a shared library is a libscn structure followed by the path name to the shared library. The C structure appears below and is defined in <scnhdr.h>.

```
struct libsen
{
                                              /* size of this entry (including target name) */
           long
                       size:
                       offset:
                                              /* offset from start of entry to target name */
           long
                       tsize;
                                              /* text size in bytes, padded to DW boundary */
           long
                       dsize;
                                              /* data size in bytes, padded to DW boundary */
           long
           long
                       bsize;
                                              /* bss size in bytes, padded to DW boundary */
           long
                       text_start; /* base of text used for this library */
                       data_start; /* base of data used for this library */
           long
                       bss_start; /* base of bss used for this library */
           long
           /* pathname of target shared library */
};
```

SEE ALSO

BUGS

The <u>s_nreloc</u> field has been known to overflow on fully linked objects when the relocation entries are saved.

scr_dump - format of curses screen image file.

SYNOPSIS

scr dump(file)

DESCRIPTION

The *curses*(3X) function *scr_dump*() will copy the contents of the screen into a file. The format of the screen image is as described below.

The name of the tty is 20 characters long and the modification time (the mtime of the tty that this is an image of) is of the type $time_t$. All other numbers and characters are stored as chtype (see <curses.h>). No newlines are stored between fields.

Only as many characters as are in a line will be listed. For example, if the line length> is 0, there will be no characters following line length>. If <labels?> is TRUE, following it will be

```
<number of labels>
<label width>
<chars in label 1>
<chars in label 2>
.
.
```

SEE ALSO

curses(3X).

services - service name data base

DESCRIPTION

The /etc/services file contains information regarding the known services available in the DARPA Internet. For each service a single line should be present with the following information:

official service name port number protocol name aliases

Items are separated by any number of blanks and/or tab characters. The port number and protocol name are considered a single *item*; a "/" is used to separate the port and protocol (e.g. "512/tcp"). A "#" indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.

Service names may contain any printable character other than a field delimiter, newline, or comment character.

YELLOW PAGES

If the NFS option is installed and Yellow Pages is running, the getservent(3N) library routines do not access this file.

FILES

/etc/services

SEE ALSO

getservent(3N)

BUGS

A name server should be used instead of a static file.

April 1990 - 1 - Version 5.0

```
syms - MIPS symbol table
```

SYNOPSIS

```
#include <sym.h>
#include <symconst.h>
```

DESCRIPTION

TABLE

The MIPS symbol table departs from the standard COFF symbol table. The symbol table consists of many tables unbundling information usually found in the one COFF symbol table. The symbol table should be viewed as a hand-crafted, network-style database designed for space and access efficiency.

The following structures or tables appear in the MIPS symbol table:

CONTENTS

sizes and locations of all other tables. symbolie header file descriptors per file locations for other tables. frame info and location of procedure info. procedure descriptors loeal type, loeal variable, and seoping info. loeal symbols string space for local symbols. local strings eompaeted by encoding, eontains a line per instruction. line numbers indirection for inter-file symbol access. relative file dese. optimization symbols to be defined. variable data type info for each local symbol. auxiliary symbols

external symbols loader symbols (global text and data).
external strings string space for external symbols.
dense numbers (file, symbol) index pairs for compiler use.

External and local symbols contain the standard concept of a "symbol" as follows:

```
struet
{
                      iss;
                                /* index into string space */
    long
                      value; /* addr, size, etc., depends on se & st */
    long
                                /* symbol type (e.g. loeal, param, etc.) */
    unsigned
                      st: 6:
                                /* storage class (e.g. text, bss, etc.) */
                      sc: 5:
    unsigned
    unsigned
                      reserved: 1;
                      index; /* index to symbol or auxiliary tables */
    unsigned
};
```

April 1990 - 1 - Version 4.0

sys_id - system identification file

DESCRIPTION

The file /etc/sys_id contains the name by which the system will be known on communications networks. The name should be no more than eight lower-case letters and digits (to maintain compatibility with foreign networks) and be terminated with a trailing newline. During system startup this file is read by the script /etc/rc2.d/S20sysetup and the contents are passed as a parameter to hostname(1) to initialize the system name. Once this has been done, this name will returned by the commands hostname(1) and uname(1) and the system calls gethostname(2) and uname(2).

FILES

/etc/sys_id

SEE ALSO

hostname(1), uname(1), gethostname(2), uname(2).

April 1990 - 1 - Version 5.0

system – system configuration information table

DESCRIPTION

This file is used by the **lboot** program to obtain configuration information. This file generally contains information used to determine if specified hardware exists, a list of software drivers to include in the load, the assignment of system devices such as *pipedev* and *swapdev*, as well as instructions for manually overriding the drivers selected by the self-configuring boot process.

The syntax of the system file is given below. The parser for the /usr/sysgen/system file is case sensitive. All upper case strings in the syntax below should be upper case in the /usr/sysgen/system file as well. Nonterminal symbols are enclosed in angle brackets "<>" while optional arguments are enclosed in square brackets "[]". Ellipses "..." indicate optional repetition of the argument for that line.

```
<fname> ::= master file name from /master.d directory
<func> ::= interrupt function name
<device> ::= special device name | DEV(<major>,<minor>)
<major> ::= <number>
<minor> ::= <number>
 ::= processor # as interpreted by runon(1)
<number> ::= decimal, octal or hex literal
```

Lboot can determine if hardware exists for a given module by use of *probe* commands. The syntax for probe commands is:

As shown from the grammar, there are two forms of probe commands. The first allows the specification of an address to read, and optionally, a number of bytes to read. If a probe address is specified, the boot program will attempt to read probe_size bytes (default 4) to determine if the hardware

exists for the module. If the read succeeds, the hardware will be assumed to exist, and the module will be included.

The extended form specifies a sequence of one or more five-tuples used to determine if the hardware exists. Each five-tuple specifies a read/write sequence, an address to read or write, a size of up to four bytes, a value, and a mask. Then, for each five-tuple, the following is performed:

```
for each element in command do

if element == 'w' then

if write(address, value & mask, size) != size then

failure

if element == 'r' then

if read(address, temp, size) != size then

failure

if temp & mask != value & mask then

failure
```

The lines listed below may appear in any order. Blank lines may be inserted at any point. Comment lines must begin with an asterisk. Entries for VECTOR, EXCLUDE and INCLUDE are cumulative. For all other entries, the last line to appear in the file is used -- any earlier entries are ignored.

```
VECTOR: (Note: this is one line) module=<fname> [ intr=<func> ]
[ vector=<number> ipl=<number> unit=<number> ] [ base2=<number> ]
[ cyrobe_cmd> ]
```

specifies hardware to conditionally load. If a probe command is specified, the boot program will perform the probe sequence, as discussed above. If the sequence succeeds, the module is included. If a probe sequence is not specified, the hardware will be assumed to exist. The intr function specifies the name of the module's interrupt handler. If it is not specified, the prefix defined in the module's master file (see master(4)) is concatenated with the string "intr", and, if a routine with that name is found in the module's object (which resides in the directory /usr/sysgen/boot, it is used as the interrupt routine. If the triplet (vector, ipl, unit, base) is specified, a VME interrupt structure is assigned, using the corresponding VME address "vector", priority level "ipl", unit "unit". If the modules' object contains a routine whose name is the concatenation of the master file prefix and "edtinit", that routine is involved once at startup and passed a pointer to an edt structure which contains the values for base, base2, base3, and a pointer to

the VME interrupt structure.

EXCLUDE: [<string>] ...

specifies drivers to exclude from the load even if the device is found via VECTOR information.

INCLUDE: [<string>[(<number>)]] ...

specifies software drivers or loadable modules to be included in the load. This is necessary to include the drivers for software "devices". The optional <number> (parenthesis required) specifies the number of "devices" to be controlled by the driver (defaults to 1). This number corresponds to the builtin variable ##c which may be referred to by expressions in part two of the /usr/sysgen/master file.

ROOTDEV: <device>

identifies the device containing the root file system.

SWAPDEV: <device> <number> <number>

identifies the device to be used as swap space, the block number the swap space starts at, and the number of swap blocks available.

PIPEDEV: <device>

identifies the device to be used for pipe space.

DUMPDEV: <device>

identifies the device to be used for kernel dumps.

IPL: <IRQ level> <proc>

send VME interrupt at <IRQ level> to <proc>. If <proc> does not exist at run time, the kernel will default to use processor 0.

NETWORKPROC:

select <proc> to handle all of kernel's networking activities. If <proc> does not exist at run time, the kernel will default to use processor 0.

USE: [<string>[(<number>)] [<extended_probe>]] ...

If the driver is present, it is the same as INCLUDE. Behaves like EXCLUDE if the module or driver is not present in /usr/sysgen/boot.

KERNEL: [<string>] ...

Specifies the module containing the heart of the operating system. It must be present in the system file.

LCOPTS

LDOPTS

are option strings given to cc(1) and ld(1) respectively, to compile the master.c file and link the operating system.

term – format of compiled term file.

SYNOPSIS

/usr/lib/terminfo/?/*

DESCRIPTION

Compiled *terminfo*(4) descriptions are placed under the directory */usr/lib/terminfo*. In order to avoid a linear search of a huge UNIX system directory, a two-level scheme is used: */usr/lib/terminfo/c/name* where *name* is the name of the terminal, and *c* is the first character of *name*. Thus, att4425 can be found in the file */usr/lib/terminfo/a/att4425*. Synonyms for the same terminal arc implemented by multiple links to the same compiled file.

The format has been chosen so that it will be the same on all hardware. An 8-bit byte is assumed, but no assumptions about byte ordering or sign extension are made. Thus, these binary terminfo(4) files can be transported to other hardware with 8-bit bytes.

Short integers are stored in two 8-bit bytes. The first byte contains the least significant 8 bits of the value, and the second byte contains the most significant 8 bits. (Thus, the value represented is 256*second+first.) The value -1 is represented by 0377,0377, and the value -2 is represented by 0376,0377; other negative values are illegal. Computers where this does not correspond to the hardware read the integers as two bytes and compute the result, making the compiled entries portable between machine types. The -1 generally means that a capability is missing from this terminal. The -2 means that the capability has been cancelled in the *terminfo* (4) source and also is to be considered missing.

The compiled file is created from the source file descriptions of the terminals (see the -I option of infocmp(1M)) by using the terminfo(4) compiler, tic(1M), and read by the routine setupterm(). (See curses(3X).) The file is divided into six parts: the header, terminal names, boolean flags, numbers, strings, and string table.

The header section begins the file. This section contains six short integers in the format described below. These integers are (1) the magic number (octal 0432); (2) the size, in bytes, of the names section; (3) the number of bytes in the boolean section; (4) the number of short integers in the numbers section; (5) the number of offsets (short integers) in the strings section; (6) the size, in bytes, of the string table.

The terminal names section comes next. It contains the first line of the terminfo(4) description, listing the various names for the terminal, separated by the bar (1) character (see term(5)). The section is terminated with an ASCII NUL character.

The boolean flags have one byte for each flag. This byte is either 0 or 1 as the flag is present or absent. The value of 2 means that the flag has been cancelled. The capabilities are in the same order as the file <term.h>.

Between the boolean section and the number section, a null byte will be inserted, if necessary, to ensure that the number section begins on an even byte. All short integers are aligned on a short word boundary.

The numbers section is similar to the boolean flags section. Each capability takes up two bytes, and is stored as a short integer. If the value represented is -1 or -2, the capability is taken to be missing.

The strings section is also similar. Each capability is stored as a short integer, in the format above. A value of -1 or -2 means the capability is missing. Otherwise, the value is taken as an offset from the beginning of the string table. Special characters in $^{\times}$ X or $^{\times}$ c notation are stored in their interpreted form, not the printing representation. Padding information ($^{\times}$ nn>) and parameter information ($^{\times}$ x) are stored intact in uninterpreted form.

The final section is the string table. It contains all the values of string capabilities referenced in the string section. Each string is null terminated.

Note that it is possible for setupterm() to expect a different set of capabilities than are actually present in the file. Either the database may have been updated since setupterm() has been recompiled (resulting in extra unrecognized entries in the file) or the program may have been recompiled more recently than the database was updated (resulting in missing entries). The routine setupterm() must be prepared for both possibilities — this is why the numbers and sizes are included. Also, new capabilities must always be added at the end of the lists of boolean, number, and string capabilities.

Some limitations: total compiled entries cannot exceed 4096 bytes; all entries in the name field cannot exceed 128 bytes.

terminfo - terminal capability data base

SYNOPSIS

/usr/lib/terminfo/?/*

DESCRIPTION

terminfo is a compiled database (see tic(1M)) describing the capabilities of terminals. Terminals are described in terminfo source descriptions by giving a set of capabilities which they have, by describing how operations are performed, by describing padding requirements, and by specifying initialization sequences. This database is used by applications programs, such as vi(1) and curses(3X), so they can work with a variety of terminals without changes to the programs. To obtain the source description for a terminal, use the $-\mathbf{I}$ option of infocmp(1M).

Entries in *terminfo* source files consist of a number of comma-separated fields. White space after each comma is ignored. The first line of each terminal description in the *terminfo* database gives the name by which *terminfo* knows the terminal, separated by bar (1) characters. The first name given is the most common abbreviation for the terminal (this is the one to use to set the environment variable TERM in \$HOME/.profile; see *profile*(4)), the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should contain no blanks and must be unique in the first 14 characters; the last name may contain blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, for example, for the AT&T 4425 terminal, att4425. Modes that the hardware can be in, or user preferences, should be indicated by appending a hyphen and an indicator of the mode. See *term*(5) for examples and more information on choosing names and synonyms.

CAPABILITIES

In the table below, the Variable is the name by which the C programmer (at the *terminfo* level) accesses the capability. The Capname is the short name for this variable used in the text of the database. It is used by a person updating the database and by the *tput*(1) command when asking what the value of the capability is for a particular terminal. The Termcap Code is a two-letter code that corresponds to the old *termcap* capability name.

Capability names have no hard length limit, but an informal limit of 5 characters has been adopted to keep them short. Whenever possible, names are chosen to be the same as or similar to the ANSI X3.64-1979 standard. Semantics are also intended to match those of the specification.

All string capabilities listed below may have padding specified, with the exception of those used for input. Input capabilities, listed under the Strings section in the table below, have names beginning with key_. The following indicators may appear at the end of the Description for a variable.

- (G) indicates that the string is passed through **tparm()** with parameters (parms) as given (#;).
- (*) indicates that padding may be based on the number of lines affected.
- $(\#_i)$ indicates the i^{th} parameter.

Variable	Cap- name	Termcap Code	Description
Booleans			
auto_left_margin	bw	bw	cub1 wraps from column 0 to last column
auto_right_margin	am	am	Terminal has automatic margins
back_color_erase	bce	bc	Screen erased with background color
can_change	ccc	сс	Terminal can re-define existing color
ceol_standout_glitch	xhp	xs	Standout not erased by overwriting (hp)
eat_newline_glitch	xenl	xn	Newline ignored after 80 cols (Concept)
erase_overstrike	eo	eo	Can erase overstrikes with a blank
generic_type	gn	gn	Generic line type (e.g. dialup, switch).
hard_copy	hc	hc	Hardcopy terminal
hard_cursor	chts	HC	Cursor is hard to see.
has_meta_key	km	km	Has a meta key (shift, sets parity bit)
has_status_line	hs	hs	Has extra "status line"
hue_lightness_saturation	hls	hl	Terminal uses only HLS color notation (Tektronix)
insert_null_glitch	in	in	Insert mode distinguishes nulls
memory_above	da	da	Display may be retained above the screen
memory_below	db	db	Display may be retained below the screen
move_insert_mode	mir	mi	Safe to move while in insert mode
move_standout_mode	msgr	ms	Safe to move in standout modes
needs_xon_xoff	nxon	nx	Padding won't work, xon/xoff required
no_esc_ctlc	xsb	xb	Beehive (f1=escape, f2=ctrl C)
non_rev_rmcup	nrmc	NR	smcup does not reverse rmcup
no_pad_char	npc	NP	Pad character doesn't exist
over_strike	os	os	Terminal overstrikes on hard-copy terminal
prtr_silent	mc5i	5i	Printer won't echo on screen.
status_line_esc_ok	eslok	es	Escape can be used on the status line
dest_tabs_magic_smso	xt	xt	Destructive tabs, magic smso char (t1061)

April 1990 - 2 - Version 5.0

tilde_glitch	hz	hz	Hazeltine; can't print tildes(")
transparent_underline	ul	ul	Underline character overstrikes
xon_xoff	xon	хо	Terminal uses xon/xoff handshaking
Numbers			
columns	cols	co	Number of columns in a line
init_tabs	it	it	Tabs initially every # spaces.
label_height	lh	lh	Number of rows in each label
label_width	lw	lw	Number of cols in each label
lines	lines	li	Number of lines on screen or page
lines_of_memory	lm	lm	Lines of memory if > lines; 0 means varies
magic_cookie_glitch	xmc	sg	Number blank chars left by smso or rmso
max_colors	colors	Co	Maximum number of colors on the screen
max_pairs	pairs	pa	Maximum number of color-pairs on the screen
no_color_video	ncv	NC	Video attributes that can't be used with colors
num_labels	nlab	NI	Number of labels on screen (start at 1)
padding_baud_rate	pb	pb	Lowest baud rate where padding needed
virtual_terminal	vt	vt	Virtual terminal number (UNIX system)
width_status_line	wsl	ws	Number of columns in status line
Strings			
acs_chars	acsc	ac	Graphic charset pairs a AbBcC - def=vt100+
back_tab	cbt	bt	Back tab
bell	bel	bl	Audible signal (bell)
carriage_retum	cr	сг	Carriage retum (*)
change_scroll_region	csr	cs	Change to lines #1 thru #2 (vt100) (G)
char_padding	mp	rР	Like ip but when in replace mode
clear_all_tabs	tbc	ct	Clear all tab stops
clear_margins	mgc	MC	Clear left and right soft margins
clear_screen	clear	cl	Clear screen and home cursor (*)
clr_bol	ell	cb	Clear to beginning of line, inclusive
clr_eol	el	ce	Clear to end of line
clr_eos	ed	cd	Clear to end of display (*)
column_address	hpa	ch	Horizontal position absolute (G)
command_character	cmdch	CC	Term. settable cmd char in prototype
cursor_address	cup	cm	Cursor motion to row #1 col #2 (G)
cursor_down	cudl	do	Down one line
cursor_home	home	ho	Home cursor (if no cup)
cursor_invisible	civis	vi	Make cursor invisible
cursor_left	cubl	le	Move cursor left one space.
cursor_mem_address	mrcup	CM	Memory relative cursor addressing (G)

April 1990 - 3 - Version 5.0

cursor_normal	cnom	ve	Make cursor appear normal (undo vs/vi)
cursor_right	cufl	nd	Non-destructive space (cursor right)
cursor_to_ll	11	11	Last line, first column (if no cup)
cursor_up	cuu l	up	Upline (cursor up)
cursor_visible	cvvis	vs	Make cursor very visible
delete_character	dch1	dc	Delete character (*)
delete_line	dl 1	dl	Delete line (*)
dis_status_line	dsl	ds	Disable status line
down_half_line	hd	hd	Half-line down (forward 1/2 linefeed)
ena_acs	enacs	eA	Enable alternate char set
enter_alt_charset_mode	smacs	as	Start alternate character set
enter_am_mode	smam	SA	Turn on automatic margins
enter_blink_mode	blink	mb	Turn on blinking
enter_bold_mode	bold	md	Turn on bold (extra bright) mode
enter_ca_mode	smcup	ti	String to begin programs that use cup
enter_delete_mode	smdc	dm	Delete mode (enter)
enter_dim_mode	dim	mh	Turn on half-bright mode
enter_insert_mode	smir	im	Insert mode (enter);
enter_protected_mode	prot	mp	Turn on protected mode
enter_reverse_mode	rev	mr	Tum on reverse video mode
enter_secure_mode	invis	mk	Turn on blank mode (chars invisible)
enter_standout_mode	smso	so	Begin standout mode
enter_underline_mode	smul	us	Start underscore mode
enter_xon_mode	smxon	SX	Turn on xon/xoff handshaking
erase_chars	ech	ec	Erase #1 characters (G)
exit_alt_charset_mode	macs	ae	End alternate character set
exit_am_mode	mam	RA	Turn off automatic margins
exit_attribute_mode	sgr0	me	Turn off all attributes
exit_ca_mode	rmcup	te	String to end programs that use cup
exit_delete_mode	rmdc	ed	End delete mode
exit_insert_mode	mir	ei	End insert mode;
exit_standout_mode	mso	se	End standout mode
exit_underline_mode	rmul	ue	End underscore mode
exit_xon_mode	mxon	RX	Turn off xon/xoff handshaking
flash_screen	flash	vb	Visible bell (may not move cursor)
form_feed	ff	ff	Hardcopy terminal page eject (*)
from_status_line	fsl	fs	Return from status line
init_1string	isl	il	Terminal initialization string
init_2string	is2	is	Terminal initialization string
init_3string	is3	i3	Terminal initialization string
init_file	if	if	Name of initialization file containing is

April 1990 - 4 - Version 5.0

init_prog	iprog	iP	Path name of program for init.
initialize_color	initc	Ic	Initialize the definition of color
initialize_pair	initp	Ip	Initialize color-pair
insert_character	ich1	ic	Insert character
insert_line	il1	a1	Add new blank line (*)
insert_padding	ip	ip	Insert pad after character inserted (*)
key_a1	ka1	K1	KEY_A1, 0534, Upper left of keypad
key_a3	ka3	K3	KEY_A3, 0535, Upper right of keypad
key_b2	kb2	K2	KEY_B2, 0536, Center of keypad
key_backspace	kbs	kb	KEY_BACKSPACE, 0407,
			Sent by backspace key
key_beg	kbeg	@1	KEY_BEG, 0542, Sent by beg(inning) key
key_btab	kcbt	kB	KEY_BTAB, 0541, Sent by back-tab key
key_c1	kc1	K4	KEY_C1, 0537, Lower left of keypad
key_c3	kc3	K5	KEY_C3, 0540, Lower right of keypad
key_cancel	kcan	@2	KEY_CANCEL, 0543, Sent by cancel key
key_catab	ktbc	ka	KEY_CATAB, 0526, Sent by clear-all-tabs key
key_clear	kclr	kC	KEY_CLEAR, 0515,
			Sent by clear-screen or erase key
key_close	kclo	@3	KEY_CLOSE, 0544, Sent by close key
key_command	kcmd	@4	KEY_COMMAND, 0545,
			Sent by cmd (command) key
key_copy	kcpy	@5	KEY_COPY, 0546, Sent by copy key
key_create	kcrt	@6	KEY_CREATE, 0547, Sent by create key
key_ctab	kctab	kt	KEY_CTAB, 0525, Sent by clear-tab key
key_dc	kdch1	kD	KEY_DC, 0512, Sent by delete-character key
key_dl	kdl1	kL	KEY_DL, 0510, Sent by delete-line key
key_down	kcud1	kd	KEY_DOWN, 0402,
			Sent by terminal down-arrow key
key_eic	krmir	kM	KEY_EIC, 0514,
			Sent by rmir or smir in insert mode
key_end	kend	@7	KEY_END, 0550, Sent by end key
key_enter	kent	@8	KEY_ENTER, 0527, Sent by enter/send key
key_eol	kel	kE	KEY_EOL, 0517,
			Sent by clear-to-end-of-line key
key_eos	ked	kS	KEY_EOS, 0516,
			Sent by clear-to-end-of-screen key
key_exit	kext	@9	KEY_EXIT, 0551, Sent by exit key
key_f0	kf0	k0	KEY_F(0), 0410, Sent by function key f0
key_f1	kf1	k1	KEY_F(1), 0411, Sent by function key f1
key_f2	kf2	k2	KEY_F(2), 0412, Sent by function key f2

April 1990 - 5 - Version 5.0

key_f3	kf3	k3	KEY_F(3), 0413, Sent by function key f3
key_f4	kf4	k4	KEY_F(4), 0414, Sent by function key f4
key_f5	kf5	k5	KEY_F(5), 0415, Sent by function key f5
key_f6	kf6	k6	KEY_F(6), 0416, Sent by function key f6
key_f7	kf7	k7	KEY_F(7), 0417, Sent by function key f7
key_f8	kf8	k8	KEY_F(8), 0420, Sent by function key f8
key_f9	kf9	k9	KEY_F(9), 0421, Sent by function key f9
key_f10	kf10	k;	KEY_F(10), 0422, Sent by function key f10
key_f11	kf11	F1	KEY_F(11), 0423, Sent by function key f11
key_f12	kf12	F2	KEY_F(12), 0424, Sent by function key f12
key_f13	kf13	F3	KEY_F(13), 0425, Sent by function key f13
key_f14	kf14	F4	KEY_F(14), 0426, Sent by function key f14
key_f15	kf15	F5	KEY_F(15), 0427, Sent by function key f15
key_f16	kf16	F6	KEY_F(16), 0430, Sent by function key f16
key_f17	kf17	F7	KEY_F(17), 0431, Sent by function key f17
key_f18	kf18	F8	KEY_F(18), 0432, Sent by function key f18
key_f19	kf19	F9	KEY_F(19), 0433, Sent by function key f19
key_f20	kf20	FA	KEY_F(20), 0434, Sent by function key f20
key_f21	kf21	FB	KEY_F(21), 0435, Sent by function key f21
key_f22	kf22	FC	KEY_F(22), 0436, Sent by function key f22
key_f23	kf23	FD	KEY_F(23), 0437, Sent by function key f23
key_f24	kf24	FE	KEY_F(24), 0440, Sent by function key f24
key_f25	kf25	FF	KEY_F(25), 0441, Sent by function key f25
key_f26	kf26	FG	KEY_F(26), 0442, Sent by function key f26
key_f27	kf27	FH	KEY_F(27), 0443, Sent by function key f27
key_f28	kf28	FI	KEY_F(28), 0444, Sent by function key f28

lab_f8	lf8	18	Labels on function key f8 if not f8
lab_f9	1f9	19	Labels on function key f9 if not f9
lab_f10	1f10	la	Labels on function key f10 if not f10
label_off	mln	LF	Turn off soft labels
label_on	smln	LO	Turn on soft labels
meta_off	mm	mo	Turn off "rneta mode"
meta_on	smm	mm	Tum on "meta mode" (8th bit)
newline	nel	nw	Newline (behaves like cr followed by If)
orig_colors	oc	oc	Set all color(-pair)s to the original ones
orig_pair	op	ор	Set default color-pair to the original one
pad_char	pad	pc	Pad character (rather than null)
parm_dch	dch	DC	Delete #1 chars (G*)
parm_delete_line	dl	DL	Delete #1 lines (G*)
parm_down_cursor	cud	DO	Move cursor down #1 lines. (G*)
parm_ich	ich	IC	Insert #1 blank chars (G*)
parm_index	indn	SF	Scroll forward #1 lines. (G)
parm_insert_line	il	AL	Add #1 new blank lines (G*)
parm_left_cursor	cub	LE	Move cursor left #1 spaces (G)
parm_right_cursor	cuf	RI	Move cursor right #1 spaces. (G*)
parm_rindex	rin	SR	Scroll backward #1 lines. (G)

April 1990 - 9 - Version 5.0

parm_up_cursor	cuu	UP	Move cursor up #1 lines. (G*)
pkey_key	pfkey	pk	Prog funct key #1 to type string #2
pkey_local	pfloc	pl	Prog funct key #1 to execute string #2
pkey_xmit	pfx	рх	Prog funct key #1 to xmit string #2
plab_norm	pln	pn	Prog label #1 to show string #2
print_screen	mc0	ps	Print contents of the screen
prtr_non	тс5р	pO	Turn on the printer for #1 bytes
prtr_off	mc4	pf	Tum off the printer
prtr_on	mc5	po	Tum on the printer
repeat_char	гер	rp	Repeat char #1 #2 times (G*)
req_for_input	rfi	RF	Send next input char (for ptys)
reset_l string	rsl	rl	Reset terminal completely to sane modes
reset_2string	rs2	r2	Reset terminal completely to sane modes
reset_3string	rs3	r3	Reset terminal completely to sane modes
reset_file	тf	rf	Name of file containing reset string
restore_cursor	rc	rc	Restore cursor to position of last sc
row_address	vpa	cv	Vertical position absolute (G)
save_cursor	sc	sc	Save cursor position.
scroll_forward	ind	sf	Scroll text up
scroll_reverse	ri	sr	Scroll text down
set_attributes	sgr	sa	Define the video attributes #1-#9 (G)
set_background	setb	Sb	Set current background color
set_bottom_margin	smgb	Zk	Set bottom margin at current line
set_bottom_margin_parm	smgbp	Z1	Set bottom margin at line #1 or #2 lines from bottom
set_color_pair	scp	sp	Set current color-pair
set_foreground	setf	Sf	Set current foreground color1
set_left_margin	smgl	ML	Set left margin at current line %374%
set_left_margin	smgl	ML	Set left margin at current line %374%
set_left_margin	smgl	ML	Set soft left margin
set_right_margin	smgr	MR	Set soft right margin
set_tab	hts	st	Set a tab in all rows, current column.
set_window	wind	wi	Current window is lines #1-#2 cols #3-#4 (G)
tab	ht	ta	Tab to next 8 space hardware tab stop.
to_status_line	tsl	ts	Go to status line, col #1 (G)
underline_char	uc	uc	Underscore one char and move past it
up_half_line	hu	hu	Half-line up (reverse 1/2 linefeed)
xoff_character	xoffc	XF	X-off character
xon_character	xonc	XN	X-on character

SAMPLE ENTRY

The following entry, which describes the *Concept*–100 terminal, is among the more complex entries in the *terminfo* file as of this writing.

April 1990 - 10 - Version 4.0

concept100 | c100 | concept | c104 | c100-4p | concept 100, am, db, eo, in, mir, ul, xenl, cols#80, lines#24, pb#9600, vt#8, bcl=\G, blank=\EH, blink=\EC, clear=\L\\$<2*>, $cnorm=\Ew, cr=^M$<9>, cub1=^H, cud1=^J,$ cuf1=\E=, cup=\Ea\%p1\%' '\%+\%c\%p2\%' '\%+\%c, $cuu1=\E$;, $cvvis=\EW$, $dch1=\E^A$<16*>$, $dim=\EE$, $d11=\E^B$<3*>, ed=\E^C$<16*>, el=\E^U$<16>,$ flash=\Ek\$<20>\EK, ht=\t\$<8>, i11=\E^R\$<3*>, ind=^J, .ind=^J\$<9>, ip=\$<16*>, is2=\EU\Ef\E7\E5\E8\ENENH\EK\E\0\Eo&\0\Eo\47\E, $kbs=^h$, $kcub1=\E>$, $kcud1=\E=$, $kcuu1=\E=$, $kf1=\E5, kf2=\E6, kf3=\E7, khome=\E?,$ prot=\EI, rcp=\Er%p1%c%p2%' '%+%c\$<.2*>, rev= \ED , rmcup= $\Ev\s\s\s\s\s\$ rmir=\E\0, rmkx=\Ex, rmso=\Ed\Ee, rmul=\Eg,

rmul=\Eg, sgr0=\EN\0, smcup=\EU\Ev\s\s8p\Ep\r, smir=\E^P, smkx=\EX, smso=\EE\ED, smul=\EG.

Entries may continue onto multiple lines by placing white space at the beginning of each line except the first.

Lines beginning with "#" are taken as comment lines.

Capabilities in

terminfo

are of three types:

boolean capabilities which indicate that the terminal has some particular feature,

numeric capabilities giving the size of the terminal or particular features, and string capabilities, which give a sequence which can be used to perform particular terminal operations.

Types of Capabilities

All capabilities have names. For instance, the fact that the *Concept* has *automatic margins* (i.e., an automatic return and linefeed when the end of a line is reached) is indicated by the capability **am**. Hence the description of the *Concept* includes **am**. Numeric capabilities are followed by the character '#' and then the value. Thus cols, which indicates the number of columns the terminal has, gives the value **80** for the *Concept*. The value may be specified in decimal, octal or hexadecimal using normal C conventions.

Finally, string-valued capabilities, such as el (clear to end of line sequence) are given by the two- to five-character capname, an '=', and then a string ending at the next following comma. A delay in milliseconds may appear anywhere in such a capability, enclosed in \$<...> brackets, as in

April 1990 - 11 - Version 5.0

el=\EK\$<3>, and padding characters are supplied by tputs() (see curses(3X)) to provide this delay. The delay can be either a number, e.g., 20, or a number followed by an '*' (i.e., 3*), a '/' (i.e., 5/), or both (i.e., 10*/). A '*' indicates that the padding required is proportional to the number of lines affected by the operation, and the amount given is the peraffected-unit padding required. (In the case of insert character, the factor is still the number of lines affected. This is always one unless the terminal has in and the software uses it.) When a '*' is specified, it is sometimes useful to give a delay of the form 3.5 to specify a delay per unit to tenths of milliseconds. (Only one decimal place is allowed.) A '/' indicates that the padding is mandatory. Otherwise, if the terminal has xon defined, the padding information is advisory and will only be used for cost estimates or when the terminal is in raw mode. Mandatory padding will be transmitted regardless of the setting of xon.

A number of escape sequences are provided in the string valued capabilities for easy encoding of characters there. Both $\$ E and $\$ e map to an ESCAPE character, $\$ x maps to a control-x for any appropriate x, and the sequences $\$ n, $\$ l, $\$ r, $\$ t, $\$ b, $\$ f, and $\$ s give a newline, linefeed, return, tab, backspace, formfeed, and space, respectively. Other escapes include: $\$ for caret ($\$); $\$ for backslash ($\$); $\$ for comma (,); $\$ for colon (:); and $\$ 0 for null. ($\$ 0 will actually produce $\$ 200, which does not terminate a string but behaves as a null character on most terminals.) Finally, characters may be given as three octal digits after a backslash (e.g., $\$ 123).

Sometimes individual capabilities must be commented out. To do this, put a period before the capability name. For example, see the second ind in the example above. Note that capabilities are defined in a left-to-right order and, therefore, a prior definition will override a later definition.

Preparing Descriptions

The most effective way to prepare a terminal description is by imitating the description of a similar terminal in *terminfo* and to build up a description gradually, using partial descriptions with vi(1) to check that they are correct. Be aware that a very unusual terminal may expose deficiencies in the ability of the **terminfo** file to describe it or the inability of vi(1) to work with that terminal. To test a new terminal description, set the environment variable TERMINFO to a pathname of a directory containing the compiled description you are working on and programs will look there rather than in *lusr/lib/terminfo*. To get the padding for insert-line correct (if the terminal manufacturer did not document it) a severe test is to comment out xon, edit a large file at 9600 baud with vi(1), delete 16 or so lines from the middle of the screen, then hit the u key several times quickly. If the display is corrupted, more padding is usually needed. A similar test can be used for insert-character.

April 1990 - 12 - Version 5.0

Basic Capabilities

The number of columns on each line for the terminal is given by the cols numeric capability. If the terminal has a screen, then the number of lines on the screen is given by the lines capability. If the terminal wraps around to the beginning of the next line when it reaches the right margin, then it should have the am capability. If the terminal can clear its screen, leaving the cursor in the home position, then this is given by the clear string capability. If the terminal overstrikes (rather than clearing a position when a character is struck over) then it should have the os capability. If the terminal is a printing terminal, with no soft copy unit, give it both hc and os. (os applies to storage scope terminals, such as Tektronix 4010 series, as well as hard-copy and APL terminals.) If there is a code to move the cursor to the left edge of the current row, give this as cr. (Normally this will be carriage return, control M.) If there is a code to produce an audible signal (bell, beep, etc) give this as bel. If the terminal uses the xon-xoff flow-control protocol, like most terminals, specify xon.

If there is a code to move the cursor one position to the left (such as back-space) that capability should be given as cub1. Similarly, codes to move to the right, up, and down should be given as cuf1, cuu1, and cud1. These local cursor motions should not alter the text they pass over; for example, you would not normally use "cuf1=\s" because the space would erase the character moved over.

A very important point here is that the local cursor motions encoded in *terminfo* are undefined at the left and top edges of a screen terminal. Programs should never attempt to backspace around the left edge, unless bw is given, and should never attempt to go up locally off the top. In order to scroll text up, a program will go to the bottom left corner of the screen and scnd the ind (index) string.

To scroll text down, a program goes to the top left corner of the screen and sends the ri (reverse index) string. The strings ind and ri are undefined when not on their respective corners of the screen.

Parameterized versions of the scrolling sequences are indn and rin which have the same semantics as ind and ri except that they take one parameter, and scroll that many lines. They are also undefined except at the appropriate edge of the screen.

The am capability tells whether the cursor sticks at the right edge of the screen when text is output, but this does not necessarily apply to a cuf1 from the last column. The only local motion which is defined from the left edge is if bw is given, then a cub1 from the left edge will move to the right edge of the previous row. If bw is not given, the effect is undefined. This is useful for drawing a box around the edge of the screen, for example. If the terminal has switch selectable automatic margins, the terminfo file

April 1990 - 13 - Version 5.0

usually assumes that this is on; i.e., am. If the terminal has a command which moves to the first column of the next line, that command can be given as nel (newline). It does not matter if the command clears the remainder of the current line, so if the terminal has no cr and If it may still be possible to craft a working nel out of one or both of them.

These capabilities suffice to describe hardcopy and screen terminals. Thus the model 33 teletype is described as

```
33 ltty33 ltty I model 33 teletype,
```

while the Lear Siegler ADM-3 is described as

adm31lsi adm3,

am, bel=^G, clear=^Z, cols#80, cr=^M, cub1=^H, cud1=^J, ind=^J, lines#24,

Parameterized Strings

Cursor addressing and other strings requiring parameters in the terminal are described by a parameterized string capability, with **printf**(3S)-like escapes (%x) in it. For example, to address the cursor, the **cup** capability is given, using two parameters: the row and column to address to. (Rows and columns are numbered from zero and refer to the physical screen visible to the user, not to any unseen memory.) If the terminal has memory relative cursor addressing, that can be indicated by **mrcup**.

The parameter mechanism uses a stack and special % codes to manipulate it in the manner of a Reverse Polish Notation (postfix) calculator. Typically a sequence will push one of the parameters onto the stack and then print it in some format. Often more complex operations are necessary. Binary operations are in postfix form with the operands in the usual order. That is, to get x-5 one would use $gx\%\{5\}$.

The % encodings have the following meanings:

```
%%
           outputs '%'
%[[:]flags][width[.precision]][doxXs]
           as in printf, flags are [-+#] and space
%с
           print pop() gives %c
           push i<sup>th</sup> parm
%p[1-9]
           set variable [a-z] to pop()
%P[a-z]
%g[a-z]
           get variable [a-z] and push it
%'c'
           push char constant c
%\{nn\}
           push decimal constant nn
%1
           push strlen(pop())
%+ %- %* %/ %m
           arithmetic (%m is mod): push(pop() op pop())
```

```
%& %l %^ bit operations: push(pop() op pop())
%= %> %<logical operations: push(pop() op pop())</li>
%A %O logical operations: and, or
%! %~ unary operations: push(op pop())
%i (for ANSI terminals)
add 1 to first parm, if one parm present, or first two parms, if more than one parm present
```

%? expr %t thenpart %e elsepart %;

if-then-else, %e elsepart is optional; else-if's are possible ala Algol 68: %? c₁ %t b₁ %e c₂ %t b₂ %e c₃ %t b₃ %e c₄ %t b₄ %e b₅%; c₁ are conditions, b₁ are bodies.

If the "-" flag is used with "%[doxXs]", then a colon (:) must be placed between the "%" and the "-" to differentiate the flag from the binary "%-" operator, e.g "%:-16.16s".

Consider the Hewlett-Packard 2645, which, to get to row 3 and column 12, needs to be sent \E&a12c03Y padded for 6 milliseconds. Note that the order of the rows and columns is inverted here, and that the row and column are zero-padded as two digits. Thus its cup capability is "cup=\E&a%p2%2.2dc%p1%2.2dY\$<6>".

The Micro-Term ACT-IV needs the current row and column sent preceded by a ^T, with the row and column simply encoded in binary, "cup=^T%p1%c%p2%c". Terminals which use "%c" need to be able to backspace the cursor (cub1), and to move the cursor up one line on the screen (cuu1). This is necessary because it is not always safe to transmit \n, ^D, and \r, as the system may change or discard them. (The library routines dealing with *terminfo* set tty modes so that tabs are never expanded, so \t is safe to send. This turns out to be essential for the Ann Arbor 4080.)

A final example is the LSI ADM-3a, which uses row and column offset by a blank character, thus "cup=\E=\%p1\%'\s'\%+\%c\%p2\%'\s'\%+\%c". After sending "\E='', this pushes the first parameter, pushes the ASCII value for a space (32), adds them (pushing the sum on the stack in place of the two previous values), and outputs that value as a character. Then the same is done for the second parameter. More complex arithmetic is possible using the stack.

Cursor Motions

If the terminal has a fast way to home the cursor (to very upper left corner of screen) then this can be given as home; similarly a fast way of getting to the lower left-hand corner can be given as II; this may involve going up with cuu1 from the home position, but a program should never do this itself (unless II does) because it can make no assumption about the effect of

April 1990 - 15 - Version 5.0

moving up from the home position. Note that the home position is the same as addressing to (0,0): to the top left corner of the screen, not of memory. (Thus, the EH sequence on Hewlett-Packard terminals cannot be used for home without losing some of the other features on the terminal.)

If the terminal has row or column absolute-cursor addressing, these can be given as single parameter capabilities hpa (horizontal position absolute) and vpa (vertical position absolute). Sometimes these are shorter than the more general two-parameter sequence (as with the Hewlett-Packard 2645) and can be used in preference to cup. If there are parameterized local motions (e.g., move *n* spaces to the right) these can be given as cud, cub, cuf, and cuu with a single parameter indicating how many spaces to move. These are primarily useful if the terminal does not have cup, such as the Tektronix 4025.

Area Clears

If the terminal can clear from the current position to the end of the line, leaving the cursor where it is, this should be given as el. If the terminal can clear from the beginning of the line to the current position inclusive, leaving the cursor where it is, this should be given as el1. If the terminal can clear from the current position to the end of the display, then this should be given as ed. ed is only defined from the first column of a line. (Thus, it can be simulated by a request to delete a large number of lines, if a true ed is not available.)

Insert/delete line

If the terminal can open a new blank line before the line where the cursor is, this should be given as il1; this is done only from the first position of a line. The cursor must then appear on the newly blank line. If the terminal can delete the line which the cursor is on, then this should be given as dl1; this is done only from the first position on the line to be deleted. Versions of il1 and dl1 which take a single parameter and insert or delete that many lines can be given as il and dl.

If the terminal has a settable destructive scrolling region (like the VT100) the command to set this can be described with the csr capability, which takes two parameters: the top and bottom lines of the scrolling region. The cursor position is, alas, undefined after using this command. It is possible to get the effect of insert or delete line using this command -- the sc and rc (save and restore cursor) commands are also useful. Inserting lines at the top or bottom of the screen can also be done using ri or ind on many terminals without a true insert/delete line, and is often faster even on terminals with those features.

April 1990 - 16 - Version 5.0

To determine whether a terminal has destructive scrolling regions or non-destructive scrolling regions, create a scrolling region in the middle of the screen, place data on the bottom line of the scrolling region, move the cursor to the top line of the scrolling region, and do a reverse index (ri) followed by a delete line (dl1) or index (ind). If the data that was originally on the bottom line of the scrolling region was restored into the scrolling region by the dl1 or ind, then the terminal has non-destructive scrolling regions. Otherwise, it has destructive scrolling regions, unless ind, ri, indn, rin, dl, and dl1 all simulate destructive scrolling.

If the terminal has the ability to define a window as part of memory, which all commands affect, it should be given as the parameterized string wind. The four parameters are the starting and ending lines in memory and the starting and ending columns in memory, in that order.

If the terminal can retain display memory above, then the da capability should be given; if display memory can be retained below, then db should be given. These indicate that deleting a line or scrolling a full screen may bring non-blank lines up from below or that scrolling back with ri may bring down non-blank lines.

Insert/Delete Character

There are two basic kinds of intelligent terminals with respect to insert/delete character operations which can be described using terminfo. The most common insert/delete character operations affect only the characters on the current line and shift characters off the end of the line rigidly. Other terminals, such as the Concept 100 and the Perkin Elmer Owl, make a distinction between typed and untyped blanks on the screen, shifting upon an insert or delete only to an untyped blank on the screen which is either eliminated, or expanded to two untyped blanks. You can determine the kind of terminal you have by clearing the screen and then typing text separated by cursor motions. Type "abc def" using local cursor motions (not spaces) between the abc and the def. Then position the cursor before the abc and put the terminal in insert mode. If typing characters causes the rest of the line to shift rigidly and characters to fall off the end, then your terminal does not distinguish between blanks and untyped positions. If the abc shifts over to the def which then move together around the end of the current line and onto the next as you insert, you have the second type of terminal, and should give the capability in, which stands for "insert null". While these are two logically separate attributes (one line versus multiline insert mode, and special treatment of untyped spaces) we have seen no terminals whose insert mode cannot be described with the single attribute.

April 1990 - 17 - Version 5.0

terminfo can describe both terminals which have an insert mode and terminals which send a simple sequence to open a blank position on the current line. Give as smir the sequence to get into insert mode. Give as rmir the sequence to leave insert mode. Now give as ich1 any sequence needed to be sent just before sending the character to be inserted. Most terminals with a true insert mode will not give ich1; terminals which send a sequence to open a screen position should give it here. (If your terminal has both, insert mode is usually preferable to ich1. Do not give both unless the terminal actually requires both to be used in combination.) If post-insert padding is needed, give this as a number of milliseconds padding in ip (a string option). Any other sequence which may need to be sent after an insert of a single character may also be given in ip. If your terminal needs both to be placed into an 'insert mode' and a special code to precede each inserted character, then both smir/rmir and ich1 can be given, and both will be used. The ich capability, with one parameter, n, will repeat the effects of ich1 n times.

If padding is necessary between characters typed while not in insert mode, give this as a number of milliseconds padding in rmp.

It is occasionally necessary to move around while in insert mode to delete characters on the same line (e.g., if there is a tab after the insertion position). If your terminal allows motion while in insert mode you can give the capability mir to speed up inserting in this case. Omitting mir will affect only speed. Some terminals (notably Datamedia's) must not have mir because of the way their insert mode works.

Finally, you can specify dch1 to delete a single character, dch with one parameter, n, to delete n characters, and delete mode by giving smdc and rmdc to enter and exit delete mode (any mode the terminal needs to be placed in for dch1 to work).

A command to erase n characters (equivalent to outputting n blanks without moving the cursor) can be given as ech with one parameter.

Highlighting, Underlining, and Visible Bells

If your terminal has one or more kinds of display attributes, these can be represented in a number of different ways. You should choose one display form as *standout mode* (see *curses*(3X)), representing a good, high contrast, easy-on-the-eyes, format for highlighting error messages and other attention getters. (If you have a choice, reverse-video plus half-bright is good, or reverse-video alone; however, different users have different preferences on different terminals.) The sequences to enter and exit standout mode are given as smso and rmso, respectively. If the code to change into or out of standout mode leaves one or even two blank spaces on the screen, as the TVI 912 and Teleray 1061 do, then xmc should be given to tell how many spaces are left.

April 1990 - 18 - Version 5.0

Codes to begin underlining and end underlining can be given as **smul** and **rmul** respectively. If the terminal has a code to underline the current character and move the cursor one space to the right, such as the Micro-Term MIME, this can be given as **uc**.

Other capabilities to enter various highlighting modes include blink (blinking), bold (bold or extra-bright), dim (dim or half-bright), invis (blanking or invisible text), prot (protected), rev (reverse-video), sgr0 (turn off all attribute modes), smacs (enter alternate-character-set mode), and rmacs (exit alternate-character-set mode). Turning on any of these modes singly may or may not turn off other modes. If a command is necessary before alternate character set mode is entered, give the sequence in enacs (enable alternate-character-set mode).

If there is a sequence to set arbitrary combinations of modes, this should be given as sgr (set attributes), taking nine parameters. Each parameter is either 0 or non-zero, as the corresponding attribute is on or off. The nine parameters are, in order: standout, underline, reverse, blink, dim, bold, blank, protect, alternate character set. Not all modes need be supported by sgr, only those for which corresponding separate attribute commands exist. (See the example at the end of this section.)

Terminals with the "magic cookie" glitch (xmc) deposit special "cookies" when they receive mode-setting sequences, which affect the display algorithm rather than having extra bits for each character. Some terminals, such as the Hewlett-Packard 2621, automatically leave standout mode when they move to a new line or the cursor is addressed. Programs using standout mode should exit standout mode before moving the cursor or sending a newline, unless the msgr capability, asserting that it is safe to move in standout mode, is present.

If the terminal has a way of flashing the screen to indicate an error quietly (a bell replacement), then this can be given as flash; it must not move the cursor. A good flash can be done by changing the screen into reverse video, pad for 200 ms, then return the screen to normal video.

If the cursor needs to be made more visible than normal when it is not on the bottom line (to make, for example, a non-blinking underline into an easier to find block or blinking underline) give this sequence as cvvis. The boolean chts should also be given. If there is a way to make the cursor completely invisible, give that as civis. The capability cnorm should be given which undoes the effects of either of these modes.

If the terminal needs to be in a special mode when running a program that uses these capabilities, the codes to enter and exit this mode can be given as **smcup** and **rmcup**. This arises, for example, from terminals like the *Concept* with more than one page of memory. If the terminal has only memory

April 1990 - 19 - Version 5.0

relative cursor addressing and not screen relative cursor addressing, a one screen-sized window must be fixed into the terminal for cursor addressing to work properly. This is also used for the Tektronix 4025, where smcup sets the command character to be the one used by terminfo. If the smcup sequence will not restore the screen after an rmcup sequence is output (to the state prior to outputting rmcup), specify nrrmc.

If your terminal generates underlined characters by using the underline character (with no special codes needed) even though it does not otherwise overstrike characters, then you should give the capability **ul**. For terminals where a character overstriking another leaves both characters on the screen, give the capability **os**. If overstrikes are erasable with a blank, then this should be indicated by giving **eo**.

Example of highlighting: assume that the terminal under question needs the following escape sequences to turn on various modes.

tparm parameter	attribute	escape sequence
	none	\E[0m
p1	standout	₹ [0;4;7m
p2	underline	₹ [0;3m
p3	reverse	₹ [0;4m
p4	blink	₹ [0;5m
p5	dim	Æ[0;7m
рб	bold	\E [0;3;4m
p7	invis	Æ[0;8m
p8	protect	not available
p9	altcharset	^O (off) ^N(on)

Note that each escape sequence requires a 0 to turn off other modes before turning on its own mode. Also note that, as suggested above, standout is set up to be the combination of reverse and dim. Also, since this terminal has no bold mode, bold is set up as the combination of reverse and underline. In addition, to allow combinations, such as underline+blink, the sequence to use would be \E[0;3;5m. The terminal doesn't have protect mode, either, but that cannot be simulated in any way, so p8 is ignored. The altcharset mode is different in that it is either O or N depending on whether it is off or on. If all modes were to be turned on, the sequence would be \E[0;3;4;5;7;8mN.

Now look at when different sequences are output. For example, ;3 is output when either **p2** or **p6** is true, that is, if either *underline* or *bold* modes are turned on. Writing out the above sequences, along with their dependencies, gives the following:

April 1990 - 20 - Version 5.0

sequence	when to output	terminfo translation
\E[0	always	\E[0
;3	if p2 or p6	%?%p2%p6%l%t;3%;
;4	if p1 or p3 or p6	%?%p1%p3%l%p6%l%t;4%;
;5	if p4	%?%p4%t;5%;
;7	if p1 or p5	%?%p1%p5%l%t;7%;
;8	if p7	%?%p7%t;8%;
m	always	m
^N or ^O	if p9 N, else O	%?%p9%t^N%e^O%;

Putting this all together into the sgr sequence gives:

sgr=\E[0%?%p2%p6%l%t;3%;%?%p1%p3%l%p6%l%t;4%;%?%p5%t; |5%;%?%p1%p5%%t;7%;%?%p7%t;8%;m%?%p9%t^N%e^O%;,

Keypad

If the terminal has a keypad that transmits codes when the keys are pressed, this information can be given. Note that it is not possible to handle terminals where the keypad only works in local (this applies, for example, to the unshifted Hewlett-Packard 2621 keys). If the keypad can be set to transmit or not transmit, give these codes as smkx and rmkx. Otherwise the keypad is assumed to always transmit.

The codes sent by the left arrow, right arrow, up arrow, down arrow, and home keys can be given as kcub1, kcub1, kcuu1, kcud1, and khome respectively. If there are function keys such as f0, f1, ..., f63, the codes they send can be given as kf0, kf1, ..., kf63. If the first 11 keys have labels other than the default f0 through f10, the labels can be given as If0, If1, ..., lf10. The codes transmitted by certain other special keys can be given: kll (home down), kbs (backspace), ktbc (clear all tabs), kctab (clear the tab stop in this column), kclr (clear screen or erase key), kdch1 (delete character), kdl1 (delete line), krmir (exit insert mode), kel (clear to end of line), ked (clear to end of screen), kich1 (insert character or enter insert mode), kil1 (insert line), knp (next page), kpp (previous page), kind (scroll forward/down), kri (scroll backward/up), khts (set a tab stop in this column). In addition, if the keypad has a 3 by 3 array of keys including the four arrow keys, the other five keys can be given as ka1, ka3, kb2, kc1, and kc3. These keys are useful when the effects of a 3 by 3 directional pad are needed. Further keys are defined above in the capabilities list.

Strings to program function keys can be given as pfkey, pfloc, and pfx. A string to program their soft-screen labels can be given as pln. Each of these strings takes two parameters: the function key number to program (from 0 to 10) and the string to program it with. Function key numbers out of this range may program undefined keys in a terminal-dependent manner. The difference between the capabilities is that pfkey causes pressing the given

April 1990 - 21 - Version 5.0

key to be the same as the user typing the given string; pttoc causes the string to be executed by the terminal in local mode; and pfx causes the string to be transmitted to the computer. The capabilities nlab, lw and lh define how many soft labels there are and their width and height. If there are commands to turn the labels on and off, give them in smln and rmln. smln is normally output after one or more pln sequences to make sure that the change becomes visible.

Tabs and Initialization

If the terminal has hardware tabs, the command to advance to the next tab stop can be given as ht (usually control I). A "backtab" command which moves leftward to the next tab stop can be given as cbt. By convention, if the teletype modes indicate that tabs are being expanded by the computer rather than being sent to the terminal, programs should not use ht or cbt even if they are present, since the user may not have the tab stops properly set. If the terminal has hardware tabs which are initially set every n spaces when the terminal is powered up, the numeric parameter it is given, showing the number of spaces the tabs are set to. This is normally used by tput init (see tput(1)) to determine whether to set the mode for hardware tab expansion and whether to set the tab stops. If the terminal has tab stops that can be saved in nonvolatile memory, the terminfo description can assume that they are properly set. If there are commands to set and clear tab stops, they can be given as tbc (clear all tab stops) and hts (set a tab stop in the current column of every row).

Other capabilities include: is1, is2, and is3, initialization strings for the terminal; iprog, the path name of a program to be run to initialize the terminal; and if, the name of a file containing long initialization strings. These strings are expected to set the terminal into modes consistent with the rest of the terminfo description. They must be sent to the terminal each time the user logs in and be output in the following order: run the program iprog; output is1; output is2; set the margins using mgc, smgl and smgr; set the tabs using tbc and hts; print the file if; and finally output is3. This is usually done using the init option of tput(1); see profile(4).

Most initialization is done with is2. Special terminal modes can be set up without duplicating strings by putting the common sequences in is2 and special cases in is1 and is3. Sequences that do a harder reset from a totally unknown state can be given as rs1, rs2, rf, and rs3, analogous to is1, is2, is3, and if. (The method using files, if and rf, is used for a few terminals, from /usr/lib/tabset/*; however, the recommended method is to use the initialization and reset strings.) These strings are output by tput reset, which is used when the terminal gets into a wedged state. Commands are normally placed in rs1, rs2, rs3, and rf only if they produce annoying effects on the screen and are not necessary when logging in. For example, the

April 1990 - 22 - Version 5.0

command to set a terminal into 80-column mode would normally be part of is2, but on some terminals it causes an annoying glitch on the screen and is not normally needed since the terminal is usually already in 80-column mode.

If a more complex sequence is needed to set the tabs than can be described by using tbc and hts, the sequence can be placed in is2 or if.

If there are commands to set and clear margins, they can be given as mgc (clear all margins), smgl (set left margin), and smgr (set right margin).

Delays

Certain capabilities control padding in the tty(7) driver. These are primarily needed by hard-copy terminals, and are used by tput init to set tty modes appropriately. Delays embedded in the capabilities cr, ind, cub1, ff, and tab can be used to set the appropriate delay bits to be set in the tty driver. If pb (padding baud rate) is given, these values can be ignored at baud rates below the value of pb.

Status Lines

If the terminal has an extra "status line" that is not normally used by software, this fact can be indicated. If the status line is viewed as an extra line below the bottom line, into which one can cursor address normally (such as the Heathkit h19's 25th line, or the 24th line of a VT100 which is set to a 23-line scrolling region), the capability hs should be given. Special strings that go to a given column of the status line and return from the status line can be given as tsl and fsl. (fsl must leave the cursor position in the same place it was before tsl. If necessary, the sc and rc strings can be included in tsl and fsl to get this effect.) The capability tsl takes one parameter, which is the column number of the status line the cursor is to be moved to.

If escape sequences and other special commands, such as tab, work while in the status line, the flag eslok can be given. A string which turns off the status line (or otherwise erases its contents) should be given as dsl. If the terminal has commands to save and restore the position of the cursor, give them as sc and rc. The status line is normally assumed to be the same width as the rest of the screen, e.g., cols. If the status line is a different width (possibly because the terminal does not allow an entire line to be loaded) the width, in columns, can be indicated with the numeric parameter wsl.

Line Graphics

If the terminal has a line drawing alternate character set, the mapping of glyph to character would be given in acsc. The definition of this string is based on the alternate character set used in the DEC VT100 terminal, extended slightly with some characters from the AT&T 4410v1 terminal.

April 1990 - 23 - Version 5.0

glyph name	vt100+
	character
arrow pointing right	+
arrow pointing left	,
arrow pointing down	•
solid square block	0
lantern symbol	I
arrow pointing up	_
diamond	4
checker board (stipple)	a
degree symbol	f
plus/minus	g
board of squares	h
lower right corner	j
upper right corner	k
upper left corner	1
lower left corner	m
plus	n
scan line 1	0
horizontal line	q
scan line 9	S
left tee (⊢)	t
right tee (-)	u
bottom tee (⊥)	v
top tee (T)	w
vertical line	X
bullet	~

The best way to describe a new terminal's line graphics set is to add a third column to the above table with the characters for the new terminal that produce the appropriate glyph when the terminal is in the alternate character set mode. For example,

April 1990 - 24 - Version 5.0

glyph name	vt100+ char	new tty char
upper left corner	1	R
lower left corner	m	F
upper right corner	k	T
lower right corner	j	G
horizontal line	q	,
vertical line	x	

Now write down the characters left to right, as in "acsc=lRmFkTjGq\x.".

Color Manipulation

Let us define two methods of color manipulation: the Tektronix method and the HP method. The Tektronix method uses a set of N predefined colors (usually 8) from which a user can select "current" foreground and background colors. Thus a terminal can support up to N colors mixed into N*N color-pairs to be displayed on the screen at the same time. When using an HP method the user cannot define the foreground independently of the background, or vice-versa. Instead, the user must define an entire color-pair at once. Up to M color-pairs, made from 2*M different colors, can be defined this way. Most existing color terminals belong to one of these two classes of terminals.

The numeric variables colors and pairs define the number of colors and color-pairs that can be displayed on the screen at the same time. If a terminal can change the definition of a color (for example, the Tektronix 4100 and 4200 series terminals), this should be specified with ccc (can change color). To change the definition of a color (Tektronix method), use initc (initialize color). It requires four arguments: color number (ranging from 0 to colors—1) and three RGB (red, green, and blue) values (ranging from 0 to 1000).

Tektronix 4100 series terminals use a type of color notation called HLS (Hue Lightness Saturation) instead of RGB color notation. For such terminals one must define a boolean variable hls. The last three arguments to the inite string would then be HLS values: H, ranging from 0 to 360; and L and S, ranging from 0 to 100.

If a terminal can change the definitions of colors, but uses a color notation different from RGB and HLS, a mapping to either RGB or HLS must be developed.

To set current foreground or background to a given color, use setf (set foreground) and setb (set background). They require one parameter: the number of the color. To initialize a color-pair (HP method), use initp (initialize pair). It requires seven parameters: the number of a color-pair

April 1990 - 25 - Version 5.0

(range=0 to pairs-1), and six RGB values: three for the foreground followed by three for the background. (Each of these groups of three should be in the order RGB.) When inite or initp are used, RGB or HLS arguments should be in the order "red, green, blue" or "hue, lightness, saturation"), respectively. To make a color-pair current, use scp (set color-pair). It takes one parameter, the number of a color-pair.

Some terminals (for example, most color terminal emulators for PCs) erase areas of the screen with current background color. In such cases, bce (background color erase) should be defined. The variable op (original pair) contains a sequence for setting the foreground and the background colors to what they were at the terminal start-up time. Similarly, oc (original colors) contains a control sequence for setting all colors (for the Tektronix method) or color-pairs (for the HP method) to the values they had at the terminal start-up time.

Some color terminals substitute color for video attributes. Such video attributes should not be combined with colors. Information about these video attributes should be packed into the nev (no color video) variable. There is a one-to-one correspondence between the nine least significant bits of that variable and the video attributes. The following table depicts this correspondence.

Attribute	Bit Position	Decimal Value
A_STANDOUT	0	1
A_UNDERLINE	1	2
A_REVERSE	2	4
A_BLINK	3	8
A_DIM	4	16
A_BOLD	5	32
A_INVIS	6	64
A_PROTECT	7	128
A_ALTCHARSET	8	256

When a particular video attribute should not be used with colors, the corresponding nev bit should be set to 1; otherwise it should be set to zero. To determine the information to pack into the nev variable, you must add together the decimal values corresponding to those attributes that cannot coexist with colors. For example, if the terminal uses colors to simulate reverse video (bit number 2 and decimal value 4) and bold (bit number 5 and decimal value 32), the resulting value for nev will be 36 (4 + 32).

April 1990 - 26 - Version 5.0

Miscellaneous

If the terminal requires other than a null (zero) character as a pad, then this can be given as pad. Only the first character of the pad string is used. If the terminal does not have a pad character, specify npc.

If the terminal can move up or down half a line, this can be indicated with **hu** (half-line up) and **hd** (half-line down). This is primarily useful for superscripts and subscripts on hardcopy terminals. If a hardcopy terminal can eject to the next page (form feed), give this as ff (usually control L).

If there is a command to repeat a given character a given number of times (to save time transmitting a large number of identical characters) this can be indicated with the parameterized string rep. The first parameter is the character to be repeated and the second is the number of times to repeat it. Thus, tparm(repeat char, 'x', 10) is the same as xxxxxxxxxx.

If the terminal has a settable command character, such as the Tektronix 4025, this can be indicated with **cmdch**. A prototype command character is chosen which is used in all capabilities. This character is given in the **cmdch** capability to identify it. The following convention is supported on some UNIX systems: If the environment variable CC exists, all occurrences of the prototype character are replaced with the character in CC.

Terminal descriptions that do not represent a specific kind of known terminal, such as switch, dialup, patch, and network, should include the gn (generic) capability so that programs can complain that they do not know how to talk to the terminal. (This capability does not apply to virtual terminal descriptions for which the escape sequences are known.) If the terminal is one of those supported by the UNIX system virtual terminal protocol, the terminal number can be given as vt. A line-turn-around sequence to be transmitted before doing reads should be specified in rfi.

If the terminal uses xon/xoff handshaking for flow control, give xon. Padding information should still be included so that routines can make better decisions about costs, but actual pad characters will not be transmitted. Sequences to turn on and off xon/xoff handshaking may be given in smxon and rmxon. If the characters used for handshaking are not 'S and 'Q, they may be specified with xonc and xoffc.

If the terminal has a "meta key" which acts as a shift key, setting the 8th bit of any character transmitted, this fact can be indicated with km. Otherwise, software will assume that the 8th bit is parity and it will usually be cleared. If strings exist to turn this "meta mode" on and off, they can be given as smm and rmm.

April 1990 - 27 - Version 5.0

If the terminal has more lines of memory than will fit on the screen at once, the number of lines of memory can be indicated with lm. A value of lm#0 indicates that the number of lines is not fixed, but that there is still more memory than fits on the screen.

Media copy strings which control an auxiliary printer connected to the terminal can be given as mc0: print the contents of the screen, mc4: turn off the printer, and mc5: turn on the printer. When the printer is on, all text sent to the terminal will be sent to the printer. A variation, mc5p, takes one parameter, and leaves the printer on for as many characters as the value of the parameter, then turns the printer off. The parameter should not exceed 255. If the text is not displayed on the terminal screen when the printer is on, specify mc5i (silent printer). All text, including mc4, is transparently passed to the printer while an mc5p is in effect.

Special Cases

The working model used by *terminfo* fits most terminals reasonably well. However, some terminals do not completely match that model, requiring special support by *terminfo*. These are not meant to be construed as deficiencies in the terminals; they are just differences between the working model and the actual hardware. They may be unusual devices or, for some reason, do not have all the features of the *terminfo* model implemented.

Terminals which can not display tilde (~) characters, such as certain Hazeltine terminals, should indicate hz.

Terminals which ignore a linefeed immediately after an am wrap, such as the *Concept* 100, should indicate xenl. Those terminals whose cursor remains on the right-most column until another character has been received, rather than wrapping immediately upon receiving the right-most character, such as the VT100, should also indicate xenl.

If el is required to get rid of standout (instead of writing normal text on top of it), xhp should be given.

Those Teleray terminals whose tabs turn all characters moved over to blanks, should indicate xt (destructive tabs). This capability is also taken to mean that it is not possible to position the cursor on top of a "magic cookie" therefore, to erase standout mode, it is instead necessary to use delete and insert line.

Those Beehive Superbee terminals which do not transmit the escape or control—C characters, should specify xsb, indicating that the f1 key is to be used for escape and the f2 key for control—C.

Similar Terminals

If there are two very similar terminals, one can be defined as being just like the other with certain exceptions. The string capability use can be given with the name of the similar terminal. The capabilities given before use override those in the terminal type invoked by use. A capability can be canceled by placing xx@ to the left of the capability definition, where xx is the capability. For example, the entry

att4424-2lTeletype 4424 in display function group ii, rev@, sgr@, smul@, use=att4424,

defines an AT&T 4424 terminal that does not have the rev, sgr, and smul capabilities, and hence cannot do highlighting. This is useful for different modes for a terminal, or for different user preferences. More than one use capability may be given.

FILES

/usr/lib/terminfo/?/* compiled terminal description database subset of compiled terminal description

database

captoinfo(1M), infocmp(1M), tic(1M), tty(7) in the System Administrator's Reference Manual.

tput(1) in the User's Reference Manual.

Chapter 9 of the Programmer's Guide.

WARNING

As described in the "Tabs and Initialization" section above, a terminal's initialization strings, is1, is2, and is3, if defined, must be output before a *curses*(3X) program is run. An available mechanism for outputting such strings is tput init (see *tput*(1) and *profile*(4)).

Tampering with entries in /usr/lib/.COREterm/?/* or /usr/lib/terminfo/?/* (for example, changing or removing an entry) can affect programs such as vi(1) that expect the entry to be present and correct. In particular, removing the description for the "dumb" terminal will cause unexpected problems.

NOTE

The *termcap* database (from earlier releases of UNIX System V) may not be supplied in future releases.

timezone - set dcfault system time zone

SYNOPSIS

/etc/TIMEZONE

DESCRIPTION

This file sets and exports the time zone environmental variable TZ.

This file is read by *init*(1) after system boot up and all subsequent processes inherit TZ in their environment.

The syntax of TZ can be described as follows:

TZ	\rightarrow	zone
		/ zone signed time
		zone signed time zone
		zone signed time zone dst
zone	\rightarrow	letter letter letter
signed time	\rightarrow	sign time
5 _		/ time
time	\rightarrow	hour
		/ hour : minute
		/ hour : minute : second
dst	\rightarrow	signed time
		/ signed_time ; dst_date , dst_date
		; dst date, dst date
dst date	\rightarrow	julian
_		julian time
letter	\rightarrow	a/A/b/B//z/Z
hour	\rightarrow	00 / 01 / / 23
minute	\rightarrow	00 01 59
second	\rightarrow	00 01 59
julian	\rightarrow	001 002 366
sign	\rightarrow	-/+·

EXAMPLES

The contents of /etc/TIMEZONE corresponding to the simple example below could be

```
# Time Zone
TZ=EST5EDT
export TZ
```

A simple setting for New Jersey could be

TZ=EST5EDT

where EST is the abbreviation for the main time zone, 5 is the difference, in hours, between GMT (Greenwich Mean Time) and the main time zone, and EDT is the abbreviation for the alternate time zone.

The most complex representation of the same setting, for the year 1986, is

TZ="EST5:00:00EDT4:00:00:117/2:00:00,299/2:00:00"

where EST is the abbreviation for the main time zone, 5:00:00 is the difference, in hours, minutes, and seconds between GMT and the main time zone, EDT is the abbreviation for the alternate time zone, 4:00:00 is the difference, in hours, minutes, and seconds between GMT and the alternate time zone, 117 is the number of the day of the year (Julian day) when the alternate time zone will take effect, 2:00:00 is the number of hours, minutes, and seconds past midnight when the alternate time zone will take effect, 299 is the number of the day of the year when the alternate time zone will end, and 2:00:00 is the number of hours, minutes, and seconds past midnight when the alternate time zone will end.

A southern hemisphere setting such as the Cook Islands could be

TZ="KDT9:30KST10:00;64/5:00,303/20:00"

This setting means that KDT is the abbreviation for the main time zone, KST is the abbreviation for the alternate time zone, KDT is 9 hours and 30 minutes later than GMT, KST is 10 hours later than GMT, the starting date of KST is the 64th day at 5 AM, and the ending date of KST is the 303rd day at 8 PM.

Starting and ending times are relative to the alternate time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be midnight.

NOTES

When the longer format is used, the TZ variable must be surrounded by double quotes as shown.

The system administrator must change the Julian start and end days annually if the longer form of the TZ variable is used.

Setting the time during the interval of change from the main time zone to the alternate time zone or vice versa can produce unpredictable results.

transferdevice - a shell script specification for extending the WorkSpace menu functions

SYNOPSIS

transferdevice menu transferdevice versionsOK

DESCRIPTION

transferdevices are shell scripts that implement one or more possible menu actions and are recognized by the standard WorkSpace file typing rules. The transfermanager is used to select and customize transfer devices on a per user bases.

Transfer devices must reside in either the directory /etc/transferDevices or \$HOME/.workspace/locatTransferLinks, and follow a set of conventions to be recognized as such.

The second line of the transfer device (the line after the shell invocation) must read

#transferDevName

where Name may be any addition to the "transferDev" prefix. If it is desired that a special icon be associated with a device, corresponding FTR and ICON rules must be constructed.

There are two command line arguments that all transfer devices must understand. Both menu and versionsOK are used by WorkSpace or the Transfer Manager. In response to a menu argument, a transfer device returns a number of lines to stdout. Each line consists of a text token, a space and string of text. Each text token corresponds to an action that the particular transfer device is designed to implement. The text string is used to describe that action.

In answer to the versionsOK argument, the device is expected to return (to stdout) either or both of the strings "local" and "remote" (seperated by a space). A response of local indicates that the transfer device may be invoked "as is." A response of "remote" means that if a symbolic link is created from the file *transferdevice.machine* to *transferdevice*, any invocation of *transferdevice.machine* will be understood by the transfer device to mean that the action should be carried out on the remote machine.

ttytype – data base of terminal types by port

SYNOPSIS

/etc/ttytype

DESCRIPTION

Ttytype is a database containing, for each tty port on the system, the kind of terminal that is attached to it. There is one line per port, containing the terminal kind (as a name listed in termcap(4)), a space, and the name of the tty, minus /dev/.

This information is read by tset(1) and by login(1) to initialize the TERM environment variable at login time.

EXAMPLE

```
iris-ansi console
iris-ansi systty
vt100
       ttyd1
?h19
        ttyd2
?h19
        ttyd3
?v50am ttyd4
?v50am ttyd5
?v50am ttyd6
?v50am ttyd7
?v50am ttyd8

unistd – file header for symbolic constants

SYNOPSIS

#include <unistd.h>

#define PF_PATH

DESCRIPTION

The header file *<unistd.h>* lists the symbolic constants and structures not already defined or declared in some other header file.

```
/* Symbolic constants for the "access" routine: */
```

```
/*Test for Read permission */
#define R_OK
                      4
                                  /*Test for Write permission */
#define W_OK
                      2
#define X_OK
                      1
                                  /*Test for eXecute permission */
                                  /*Test for existence of File */
#define F_OK
                      0
#define F ULOCK
                                  /*Unlock a previously locked region */
                      0
                                  /*Lock a region for exclusive use */
#define F_LOCK
                      1
                                  /*Test and lock a region for exclusive use *
#define F_TLOCK
                      2
#define F_TEST
                      3
                                  /*Test a region for other processes locks */
/*Symbolic constants for the "lseck" routine: */
                                  /* Set file pointer to "offset" */
#define SEEK SET
#define SEEK_CUR 1
                                  /* Set file pointer to current plus "offset" */
                                  /* Set file pointer to EOF plus "offset" */
#define SEEK_END
                      2

utmp, wtmp - utmp and wtmp entry formats

SYNOPSIS

```
#include <sys/types.h>
#include <utmp.h>
```

DESCRIPTION

These files, which hold user and accounting information for such commands as who(1), write(1), and login(1), have the following structure as defined by <utmp.h>:

```
#define
                           "/etc/utmp"
           UTMP_FILE
#define
           WTMP_FILE
                           "/etc/wtmp"
#define
          ut_name
                          .ut_user
struct utmp {
                                   /* User login name */
      char
                 ut_user[8];
                                   /* /etc/inittab id (usually line #) */
      char
                 ut_id[4];
                                   /* device name (console, lnxx) */
      char
                 ut_line[12];
                 ut_pid;
                                   /* process id */
      short
                                   /* type of entry */
      short
                ut_type;
                exit_status {
      struct
                   e_termination; /* Process termination status */
         short
                                   /* Process exit status */
         short
                   e_exit;
                                   /* The exit status of a process
      } ut_exit;
                                    * marked as DEAD_PROCESS. */
      time_t
                ut_time;
                                   /* time entry was made */
};
```

```
/* Definitions for ut_type */
        #define EMPTY
                                 0

uuencode - format of an encoded uuencode file

DESCRIPTION

Files output by uuencode(1C) consist of a header line, followed by a number of body lines, and a trailer line. Uudecode(1C) will ignore any lines preceding the header or following the trailer. Lines preceding a header must not, of course, look like a header.

The header line is distinguished by having the first 6 characters "begin". The word *begin* is followed by a mode (in octal), and a string which names the remote file. A space separates the three items in the header line.

The body consists of a number of lines, each at most 62 characters long (including the trailing newline). These consist of a character count, followed by encoded characters, followed by a newline. The character count is a single printing character, and represents an integer, the number of bytes the rest of the line represents. Such integers are always in the range from 0 to 63 and can be determined by subtracting the character space (octal 40) from the character.

Groups of 3 bytes are stored in 4 characters, 6 bits per character. All are offset by a space to make the characters printing. The last line may be shorter than the normal 45 bytes. If the size is not a multiple of 3, this fact can be determined by the value of the count on the last line. Extra garbage will be included to make the character count a multiple of 4. The body is terminated by a line with a count of zero. This line consists of one ASCII space.

The trailer line consists of "end" on a line by itself.

visuallogin, noiconlogin - select and control console login program

DESCRIPTION

The configuration flag *visuallogin* selects the type of login program used for the graphics console. If *visuallogin* is on, the visual login program pandora(1) used for logins. If it is off, the standard IRIX login(1) program is used.

If the configuration flag *noiconlogin* is *on*, *pandora*(1) displays icons for each user. If it is off, icons are not displayed.

The value of the flags can be set to on or off using chkconfig (1M).

FILES

/etc/config/visuallogin /etc/config/noiconlogin

intro - introduction to miscellany

DESCRIPTION

This section describes miscellaneous facilities such as macro packages, character set tables, etc.

ascii - map of ASCII character set

DESCRIPTION

ascii is a map of the ASCII character set, giving both octal and hexadecimal equivalents of each character, to be printed as needed. It contains:

charset - description of the standard supported character set

DESCRIPTION

A single 8-bit character set, based on ISO 8859-1, is currently supported. Other character sets may be supported in the future.

ISO 8859-1 is an 8-bit single-byte coded character set. This set, Latin Alphabet #1, contains characters used for general purpose applications in typical office environments in at least the following languages: Danish, Dutch, English, Faeroese, Finnish, French, German, Icelandic, Irish, Italian, Norwegian, Portuguese, Spanish, and Swedish.

(NOTE: please see this man page in the IRIS-4D Programmer's Reference Manual for the table of characters.)

The ASCII 7-bit character set is a proper subset of 8859-1 (see ASCII(5)). The characters added by ISO 8859-1 each have the most significant bit of the byte on.

environ – user environment

DESCRIPTION

An array of strings called the "environment" is made available by exec (2) when a process begins. By convention, these strings have the form "name=value". The following names are used by various commands:

CFTIME

The default format string to be used by the date (1) command and the ascftime() and cftime() routines (see ctime(3C)). If CFTIME is not set or is null, the default format string specified in the /lib/cftime/LANGUAGE file (if it exists) is used in its place (see cftime(4)).

CHRCLASS

A value that corresponds to a file in /lib/chrclass containing character classification and conversion information. This information is used

by commands (such as cat(1), ed(1), sort(1), etc.) to classify characters as alphabetic, printable, upper case, etc. and to convert characters to upper or lower case.

When a program or command begins execution, the tables containing this information are initialized based on the value of CHRCLASS. If CHRCLASS is non-existent, null, set to a value for which no file exists in /lib/chrclass, or errors occur while reading the file, the ASCII character set is used. During execution, a program or command can change the values in these tables by calling the setchrelass() routine. For more dctail, see ctype (3C).

These tables are created using the *chrtbl*(1M) command.

HOME

The name of the user's login directory, set by login(1) from the password file (see passwd(4)).

LANGUAGE A language for which a printable file by that name exists in /lib/cftime. This information is used by commands (such as date(1), ls(1), sort(1), etc.) to print date and time information in the language specified.

> If LANGUAGE is non-existent, null, set to a value for which no file exists in /lib/cftime, or errors occur while reading the file, the last language requested will be used. (If no language has been requested, the language usa english is assumed.) For a description of the content of files in /lib/cftime, see cftime(4).

PATH

The sequence of directory prefixes that sh(1), time(1), nice(1), nohup(1), etc., apply in searching for a file known by an incomplete path name. The prefixes are separated by colons (:). login(1) sets PATH=:/usr/sbin:/usr/bsd:/bin:/usr/bin:/usr/bin/X11. (For more detail, see the "Execution" section of the sh(1) manual page.)

manuai pa

TERM

The kind of terminal for which output is to be prepared. This information is used by commands, such as more(1) or vi(1), which may exploit special capabilities of that terminal.

USER

The user name (from the password file) of the user which is currently running. It is set by login(1), su(1), rlogind(1M), newgrp(1), and cron(1).

LOGNAME S

Synonymous with USER.

SHELL

The path to the user's shell, set from the password file.

TZ

Time zone information. The simplest format is xxxnzzz where xxx is the standard local time zone abbreviation, n is the difference in hours from GMT (Greenwich Mean Time), and zzz is the abbreviation for an alternate time zone (usually the daylight-saving local time zone), if any; for example,

TZ="EST5EDT"

The most complex format allows you to specify the difference in hours of the alternate time zone from GMT and the starting day and time and ending day and time for using this alternate time zone. For example, in 1985 the complex format corresponding to the above simple example is:

TZ="EST5:00:00EDT4:00:00;118/2:00:00,300/2:00:00"

When the above complex format is used, it must be surrounded by double quotes. For more details, see *ctime*(3C) and *timezone*(4).

Further names may be placed in the environment by the *export* command and "name=value" arguments in sh(1), by the *setenv* command in csh(1), or by exec(2). It is unwise to conflict with certain shell variables that are frequently exported by .profile or .cshrc files: MAIL, PS1, PS2, IFS (see profile(4) and cshrc(4)).

NOTES

Administrators should note the following: if you attempt to set the current date to one of the dates that the standard and alternate time zones change (for example, the date that daylight time is starting or ending), and you

attempt to set the time to a time in the interval between the end of standard time and the beginning of the alternate time (or the end of the alternate time and the beginning of standard time), the results are unpredictable.

fcntl – file control options

SYNOPSIS

#include <fcntl.h>

DESCRIPTION

The fcntl(2) function provides for control over open files. This include file describes requests and arguments to fcntl and open(2).

```
/* fcntl(2) requests */
#define F_DUPFD 0
                           /* Duplicate fildes */
#define F_GETFD 1
                           /* Get fildes flags */
#define F SETFD 2
                           /* Set fildes flags */
#define F_GETFL 3
                           /* Get file flags */
#define F_SETFL
                                     /* Set file flags */
#define F_GETLK 5
                           /* Get file lock */
#define F_SETLK 6

hostname - host name resolution description

DESCRIPTION

Hostnames are domains, where a domain is a hierarchieal, dot-separated list of subdomains; for example, the machine monet, in the Berkeley subdomain of the EDU subdomain of the Internet would be represented as

monet.Berkeley.EDU (with no trailing dot).

Hostnames are often used with network elient and server programs, which must generally translate the name to an address for use. (This function is generally performed by the library routine *gethostbyname*(3N).) Hostnames are resolved by the Internet name resolver in the following fashion.

If the name consists of a single eomponent, i.e., contains no dot, and if the environment variable "HOSTALIASES" is set to the name of a file, that file is searched for a string matching the input hostname. The file should eonsist of lines made up of two white-space separated strings, the first of which is the hostname alias, and the second of which is the complete hostname to be substituted for that alias. For example, to refer to the host "matisse.painters.org" with the alias "henri", use

henri matisse.painters.org

If a ease-insensitive match is found between the hostname to be resolved and the first field of a line in the file, the substituted name is looked up with no further processing.

If the input name ends with a trailing dot, the trailing dot is removed, and the remaining name is looked up with no further processing.

If the input name does not end with a trailing dot, it is looked up by searching through a list of domains until a match is found. The default search list includes first the local domain, then its parent domains with at least 2 name components (longest first). For example, in the domain CS.Berkeley.EDU, lithium.CChem the name will be cheeked first lithium.CChem.CS.Berkeley.EDU and then lithium.CChem.Berkeley.EDU. Lithium.CChem.EDU will not be tried, as there is only one component remaining from the local domain. The search path ean be ehanged from the default by the resolv.conf system-wide eonfiguration file. See the descriptions of the search keyword in resolver (4).

math – math functions and constants

SYNOPSIS

#include <math.h>

DESCRIPTION

This file contains declarations of all the functions in the Math Library (described in Section 3M), as well as various functions in the C Library (Section 3C) that return floating-point values.

It defines the following constant used as an error-return value:

HUGE The maximum value of a single-precision

floating-point number

The following mathematical constants are defined for user convenience:

M_E The base of natural logarithms (e)

M_LOG2E The base-2 logarithm of e

M_LOG10E The base-10 logarithm of e

M_LN2 The natural logarithm of 2

M_LN10 The natural logarithm of 10

M_PI Pi (the ratio of the circumference of a circle to its

diameter)

M_SQRT2 The positive square root of 2
M_SQRT1_2 The positive square root of 1/2

For the definitions of various machine-dependent "constants," see the description of the *<values.h>* header file.

regexp - regular expression compile and match routines

SYNOPSIS

```
#define INIT <declarations>
#define GETC() <getc code>
#define PEEKC() <peekc code>
#define UNGETC(c) <ungetc code>
#define RETURN(pointer) <return code>
#define ERROR(val) <error code>
#include <regexp.h>
char *compile (instring, expbuf, endbuf, eof)
char *instring, *expbuf, *endbuf;
int eof;
int step (string, expbuf)
char *string, *expbuf;
extern char *loc1, *loc2, *locs;
extern int circf, sed, nbra;
```

DESCRIPTION

This page describes general-purpose regular expression matching routines in the form of ed(1), defined in <regexp.h>. Programs such as ed(1), sed(1), grep(1), expr(1), etc., which perform regular expression matching use this source file. In this way, only this file need be changed to maintain regular expression compatibility.

The interface to this file is unpleasantly complex. Programs that include this file must have the following five macros declared before the "#include <regexp.h>" statement. These macros are used by the *compile* routine.

GETC() Return the value of the next character in the reg
--

lar expression pattern. Successive calls to GETC() should return successive characters of the regular

expression.

PEEKC() Return the next character in the regular expression.

Successive calls to PEEKC() should return the same character [which should also be the next

character returned by GETC()].

UNGETC(c) Cause the argument c to be returned by the next

call to GETC() [and PEEKC()]. No more that one character of pushback is ever needed and this character is guaranteed to be the last character read by

REGEXP	(5	•

GETC().	The	value	of	the	macro	UNGETC(c)	is
always io	nore	1.					

RETURN(pointer)

This macro is used on normal exit of the *compile* routine. The value of the argument *pointer* is a pointer to the character after the last character of the compiled regular expression. This is useful to programs which have memory allocation to manage.

ERROR(val)

This is the abnormal return from the *compile* routine. The argument *val* is an error number (see table below for meanings). This call should never return.

ERROR	MEANING
11	Range endpoint too large.
16	Bad number.
25	"\digit" out of range.
36	Illegal or missing delimiter.
41	No remembered search string.
42	\(\) imbalance.
43	Too many \(.
44	More than 2 numbers given in $\{ \}$.
45	} expected after \.
46	First number exceeds second in \{ \}.
49	[] imbalance.
50	Regular expression overflow.

The syntax of the *compile* routine is as follows:

compile(instring, expbuf, endbuf, eof)

The first parameter *instring* is never used explicitly by the *compile* routine but is useful for programs that pass down different pointers to input characters. It is sometimes used in the INIT declaration (see below). Programs which call functions to input characters or have characters in an external array can pass down a value of ((char *) 0) for this parameter.

The next parameter *expbuf* is a character pointer. It points to the place where the compiled regular expression will be placed.

The parameter *endbuf* is one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (*endbuf*-*expbuf*) bytes, a call to ERROR(50) is made.

The parameter eof is the character which marks the end of the regular expression. For example, in ed(1), this character is usually a l.

Each program that includes this file must have a #define statement for INIT. This definition will be placed right after the declaration for the function compile and the opening curly brace ({). It is used for dependent declarations and initializations. Most often it is used to set a register variable to point the beginning of the regular expression so that this register variable can be used in the declarations for GETC(), PEEKC() and UNGETC(). Otherwise it can be used to declare external variables that might be used by GETC(), PEEKC() and UNGETC(). See the example below of the declarations taken from grep(1).

There are other functions in this file which perform actual regular expression matching, one of which is the function *step*. The call to *step* is as follows:

step(string, expbuf)

The first parameter to *step* is a pointer to a string of characters to be checked for a match. This string should be null terminated.

The second parameter *expbuf* is the compiled regular expression which was obtained by a call of the function *compile*.

The function *step* returns non-zero if the given string matches the regular expression, and zero if the expressions do not match. If there is a match, two external character pointers are set as a side effect to the call to *step*. The variable set in *step* is *loc1*. This is a pointer to the first character that matched the regular expression. The variable *loc2*, which is set by the function *advance*, points to the character after the last character that matches the regular expression. Thus if the regular expression matches the entire line, *loc1* will point to the first character of *string* and *loc2* will point to the null at the end of *string*.

Step uses the external variable *circf* which is set by *compile* if the regular expression begins with ^. If this is set then *step* will try to match the regular expression to the beginning of the string only. If more than one regular expression is to be compiled before the first is executed the value of *circf* should be saved for each compiled expression and *circf* should be set to that saved value before each call to *step*.

The function *advance* is called from *step* with the same arguments as *step*. The purpose of *step* is to step through the *string* argument and call *advance* until *advance* returns non-zero indicating a match or until the end of *string* is reached. If one wants to constrain *string* to the beginning of the line in all cases, *step* need not be called; simply call *advance*.

When advance encounters a * or \{ \} sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, advance will back up along the string until it finds a match or reaches the point in the string that initially matched the * or \{ \}. It is sometimes desirable to stop this backing up before the initial point in the string is reached. If the external character pointer locs is equal to the point in the string at sometime during the backing up process, advance will break out of the loop that backs up and will return zero. This is used by ed(1) and sed(1) for substitutions done globally (not just the first occurrence, but the whole line) so, for example, expressions like s/y*//g do not loop forever.

The additional external variables sed and nbra are used for special purposes.

EXAMPLES

The following is an example of how the regular expression macros and calls look from grep(1):

```
#define INIT
                            register char *sp = instring;
#define GETC()
                            (*sp++)
                            (*sp)
#define PEEKC()
#define UNGETC(c)
                            (---sp)
#define RETURN(c)
                            return;
#define ERROR(c)
                            regerr()
#include <regexp.h>
                  (void) compile(*argv, expbuf, &expbuf[ESIZE], \0');
                   if (step(linebuf, expbuf))
                                      succeed();
```

stat - data returned by stat system call

SYNOPSIS

```
#include <sys/types.h>
#include <sys/stat.h>
```

DESCRIPTION

The system calls *stat* and *fstat* return data whose structure is defined by this include file. The encoding of the field *st mode* is defined in this file also.

Structure of the result of stat

```
struct
        stat
        ino_t
                   st_ino;
                   st_dev;
        dev_t
                   st_mode;
        mode_t
        short
                   st_nlink;
        ushort
                  st_uid;
        ushort
                  st_gid;
                   st_rdev;
        dev_t
        off_t
                  st_size;
        time_t
                  st_atime;
        time t
                   st mtime;
                  st_ctime;

stdarg - variable argument list

SYNOPSIS

```
#include <stdarg.h>
void va_start (va_list ap, ParmN);
type va_arg (va_list ap, type);
void va end (va_list ap);
```

DESCRIPTION

This set of macros provides a means of writing portable procedures that accept variable argument lists. Routines having variable argument lists (such as *printf*(3)) that do not use stdarg are inherently nonportable, since different machines use different argument passing conventions. The stdarg facility is similar to *varargs*(5), but is based on the ANSI Standard for C.

A variable argument list contains one or more parameters. The rightmost parameter plays a special role, and is designated *ParmN* in this discussion.

va_list is a type suitable for storing information needed by the macros va_start, va_arg, and va_end. The called function must declare a variable (referred to as ap) of type va list, used to access the argument list.

The va_start (ap, ParmN) macro initializes ap for subsequent use by va_arg and va_end. va_start must be called before any use of va_arg.

The va_arg (ap, type) macro will return the next argument in the list pointed to by ap. The first invocation of va_arg returns the value of the argument after that specified by ParmN. Successive invocations return the values of the remaining arguments in succession. type is the type to which the expected argument will be converted when passed as an argument. In standard C, arguments that are char or short should be accessed as int, unsigned char or unsigned short are converted to unsigned int, and float arguments are converted to double. Different types can be mixed, but it is up to the routine to know what type of argument is expected.

va end (ap) is used to finish up.

Multiple traversals, each bracketed by va start ... va end, are possible.

EXAMPLE

```
#include <stdarg.h>
#define MAXARGS 31

void f1(int nptrs, ...)
{

va_list ap;
char *array[MAXARGS];
```

BUGS

Due to the procedure calling convention on the MIPS processor, floating-point parameters may be inaccessible via *stdarg* unless they appear *after* a parameter of non-floating-point type. Thus, in the code sequence

```
extern int foo(float,...);
```

```
foo(1.0,2.0);
```

the parameter 2.0 may be accessed incorrectly. If the function expected an intervening non-floating-point parameter, such as

```
extern int foo(float,...);
```

```
foo(1.0,4,2.0);
```

the second floating-point parameter would be accessible as a *double*. No problem is encountered, of course, if the type of the first argument is not floating-point.

Stdarg cannot be used when passing structures as parameters, as it is impossible to determine their alignment at runtime.

It is up to the ealling routine to determine how many arguments there are, since it is not possible to determine this from the stack frame. For example, *execl* passes a 0 to signal the end of the list. *Printf* ean tell how many arguments are supposed to be there by the format.

The macros va_start and va_end may be arbitrarily complex; for example, va_start might contain an opening brace, which is closed by a matching brace in va_end . Thus, they should only be used where they could be placed within a single complex statement.

term - conventional names for terminals

DESCRIPTION

These names are used by certain commands (e.g., man(1), tabs(1), tput(1), vi(1) and curses(3X)) and are maintained as part of the shell environment in the environment variable TERM (see sh(1), profile(4), and environ(5)).

Entries in *terminfo*(4) source files consist of a number of comma-separated fields. (To obtain the source description for a terminal, use the –I option of *infocmp*(1M).) White space after each comma is ignored. The first line of each terminal description in the *terminfo*(4) database gives the names by which *terminfo*(4) knows the terminal, separated by bar (1) characters. The first name given is the most common abbreviation for the terminal (this is the one to use to set the environment variable TERMINFO in \$HOMEI.profile; see *profile*(4)), the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should contain no blanks and must be unique in the first 14 characters; the last name may contain blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, for example, for the AT&T 4425 terminal, att4425. This name should not contain hyphens, except that synonyms may be chosen that do not conflict with other names. Up to 8 characters, chosen from [a–z0–9], make up a basic terminal name. Names should generally be based on original vendors, rather than local distributors. A terminal acquired from one vendor should not have more than one distinct basic name. Terminal sub-models, operational modes that the hardware can be in, or user preferences, should be indicated by appending a hyphen and an indicator of the mode. Thus, an AT&T 4425 terminal in 132 column mode would be att4425—w. The following suffixes should be used where possible:

Suffix	Meaning	Example
$-\mathbf{w}$	Wide mode (more than 80 columns)	att4425-w
-am	With auto. margins (usually default)	vt100–am
-nam	Without automatic margins	vt100-nam
-n	Number of lines on the screen	aaa-60
-na	No arrow keys (leave them in local)	c100-na
-np	Number of pages of memory	c100-4p
-rv	Reverse video	att4415-rv

To avoid eonfliets with the naming eonventions used in describing the different modes of a terminal (e.g., -w), it is recommended that a terminal's root name not eontain hyphens. Further, it is good practice to make all terminal names used in the *terminfo(4)* database unique. Terminal entries that are present only for inclusion in other entries via the use= facilities should have a '+' in their name, as in 4415+nl.

Some of the known terminal names may include the following (for a complete list, type: ls -C /usr/lib/terminfo/?):

types - primitive system data types

SYNOPSIS

#include <sys/types.h>

DESCRIPTION

The data types defined in the include file are used in IRIX system code; some data of these types are accessible to user code:

```
typedef struct { int r[1]; } *physadr;
typedef long
                       daddr_t;
typedef ehar *
                       caddr_t;
typedef unsigned ehar unehar;
typedef unsigned short ushort;
typedef unsigned int
                       uint;
typedef unsigned long ulong;
typedef ulong
                       ino_t;
typedef short
                       cnt_t;
typedef long
                       time_t;
typedef int
                       label_t[12];
typedef short
                       dev_t;
typedef long
                       off t;
typedef unsigned long paddr_t;
typedef int
                       key_t;
typedef unsigned char use_t;
typedef short
                       sysid_t;
typedef short
                       index_t;
typedef unsigned int
                       lock_t;
typedef unsigned int
                       size_t;
typedef unsigned ehar u_ehar;
typedef unsigned short u_short;
typedef unsigned int
                       u_int;
typedef unsigned long u_long;
```

The form $daddr_t$ is used for disk addresses except in an i-node on disk, see fs(4). Times are encoded in seconds since 00:00:00 GMT, January 1, 1970. The major and minor parts of a device code specify kind and unit number of a device and are installation-dependent. Offsets are measured in bytes from the beginning of a file. The $label_t$ variables are used to save the processor state while another process is running.

SEE ALSO fs(4).

values - machine-dependent values

SYNOPSIS

#include <values.h>

DESCRIPTION

This file eontains a set of manifest eonstants, eonditionally defined for particular processor architectures.

The model assumed for integers is binary representation (one's or two's complement), where the sign is represented by the value of the high-order bit.

BITS(type) The number of bits in a specified type (e.g., int).

HIBITS The value of a short integer with only the high-

order bit set (in most implementations, 0x8000).

HIBITL The value of a long integer with only the high-

order bit set (in most implementations,

0x80000000).

HIBITI The value of a regular integer with only the high-

order bit set (usually the same as HIBITS or

HIBITL).

MAXSHORT The maximum value of a signed short integer (in

most implementations, 0x7FFF = 32767).

MAXLONG The maximum value of a signed long integer (in

most implementations, 0x7FFFFFFF \equiv

2147483647).

MAXINT The maximum value of a signed regular integer

(usually the same as MAXSHORT or MAXLONG).

MAXFLOAT, LN_MAXFLOAT The maximum value of a single-

precision floating-point number, and

its natural logarithm.

MAXDOUBLE, LN_MAXDOUBLE The maximum value of a double-

precision floating-point number, and

its natural logarithm.

MINFLOAT, LN_MINFLOAT The minimum positive value of a

single-precision floating-point

number, and its natural logarithm.

MINDOUBLE, LN_MINDOUBLE The minimum positive value of a

double-precision floating-point number, and its natural logarithm.

FSIGNIF The number of significant bits in the mantissa of a

single-precision floating-point number.

The number of significant bits in the mantissa of a DSIGNIF

double-precision floating-point number.

SEE ALSO

varargs - variable argument list

SYNOPSIS

```
#include <varargs.h>
function(va_alist)
va_dcl
va_list pvar;
va_start(pvar);
f = va_arg(pvar, type);
va end(pvar);
```

DESCRIPTION

This set of macros provides a means of writing portable procedures that accept variable argument lists. Routines having variable argument lists (such as *printf*(3)) that do not use varargs are inherently nonportable, since different machines use different argument passing conventions.

va alist is used in a function header to declare a variable argument list.

va_dcl is a declaration for va_alist. Note that there is no semicolon after va dcl.

va_list is a type which can be used for the variable *pvar*, which is used to traverse the list. One such variable must always be declared.

va start(pvar) is called to initialize pvar to the beginning of the list.

va_arg(pvar, type) will return the next argument in the list pointed to by pvar. Type is the type to which the expected argument will be converted when passed as an argument. In standard C, arguments that are char or short should be accessed as int, unsigned char or unsigned short are converted to unsigned int, and float arguments are converted to double. Different types can be mixed, but it is up to the routine to know what type of argument is expected, since it cannot be determined at runtime.

va end(pvar) is used to finish up.

Multiple traversals, each bracketed by va_start ... va_end, are possible.

EXAMPLE

```
#include <varargs.h>
execl(va_alist)
va_dcl
{
     va_list ap;
     char *file;
     char *args[100];
     int argno = 0;
```

April 1990 - 1 - Version 5.0

```
va_start(ap);
file = va_arg(ap, char *);

BUGS

Due to the procedure calling convention on the MIPS processor, floating-point parameters may be inaccessible via *varargs* unless they appear *after* a parameter of non-floating-point type. Thus, in the code sequence

```
extern int foo(float,...);
```

```
foo(1.0,2.0);
```

the parameter 2.0 may be accessed incorrectly. If the function expected an intervening non-floating-point parameter, such as

```
extern int foo(float,...);
```

```
foo(1.0,4,2.0);
```

the second floating-point parameter would be accessible as a double.

Varargs cannot be used when passing structures as parameters, as it is impossible to determine their alignment at runtime.

It is up to the calling routine to determine how many arguments there are, since it is not possible to determine this from the stack frame. For example, *execl* passes a 0 to signal the end of the list. *Printf* can tell how many arguments are supposed to be there by the format.

The macros va_start and va_end may be arbitrarily complex; for example, va_start might contain an opening brace, which is closed by a matching brace in va_end . Thus, they should only be used where they could be placed within a single complex statement.

April 1990 - 2 - Version 5.0

winicons - stowed window image mechanism

DESCRIPTION

When an active window is stowed by the user, an RGB image file may be used to paint the canvas of the stowed window icon. A window icon file must contain the suffix .icon.

Window icons are assigned to stowed windows by matching the name that appears in the program's call to the Graphics Library subroutine, winopen. Thus, an icon for the GL program *cedit* would have this name:

cedit.icon

WINICON SEARCH PATH

A directory of default window icons exists in \$NEWSHOME/icons. You may add or customize window icons by placing them in \$HOME/.4sight/icons. To find the appropriate window icon for a stowed window, 4Sight first searches \$HOME/.4sight/icons for a name match. If it is unsuccessful, it seaches the default window icon directory (\$NEWSHOME/icons). If this is unsuccessful, it uses the prededined icon \$NEWSHOME/icons/default.icon. If this icon is missing for some reason, 4Sight draws the icon without an image.

CREATING A WINICON FILE

A window icon can be created from any image that can be displayed on the IRIS screen (provided that the tools described below are accessible when the image is displayed).

The following passage describes one possible way to create an icon image file. First, display the image you wish to use with the image tools *ipaste* or *showci*, or simply open a window containing a program from which you want to take an image (make sure that the image is still). Then invoke the image tool *icut* from the command line. *icut* takes a filename as an argument; the image cut from the screen is written to that file.

icut foo

Place the small rectagular *icut* window away from the image you wish to cut. Place the mouse cursor inside the icut window and hold down the <shift> key. While holding down the key, move the mouse cursor to the upper left corner of the area you wish to cut. Hold down the left mouse button while you move to the lower right corner of the area you wish to cut (the area is not shown on the screen), and when you are ready, lct go of the left button. The image is then written to the file.

April 1990 - 1 - Version 5.0

Note: The image you cut must be scaled to fit the stowed window canvas, so you should attempt to cut an area of the same general shape as the icon. The ratio of window icon width to height is 64:50.

You can use the file obtained with *icut* as a window icon file, and 4Sight will scale and dither it on the fly. However, to increase efficiency and image quality, you may want to scale it yourself. To do so, first run the image tool *istat* on the *icut* file:

```
istat foo
```

istat gives a readout of various image statistics; the important ones for scaling are the first two values, the image width (xsize) and image height (ysize). The dimension of stowed windows is 50 NeWS (4Sight) points high by 64 NeWS points wide. The ratio of screen pixels to points is 4:3; this yields the following scaling factors:

```
xscale = 85.33/(xsize)

yscale = 66.67/(ysize)
```

To scale the image, use the image tool *izoom*. *izoom* takes in input file, an output file, and width and height scaling factors as arguments. To scale an image file *foo* whose dimensions are 620 pixels wide by 500 pixels high and make it into a console window icon, you would type the following on the command line:

```
izoom foo $HOME/.4sight/icons/console.icon .137 .133
```

NOTES

Some programs do not use this mechanism to draw their window icons; specifically, those that draw their own icons rather than let 4Sight do it for them. Certain NeWS programs, such as the Calculator draw their own icons in PostScript; Graphics Library programs using iconsize to draw their icons use Graphics Library commands to do so. Both of these methods override the window icon mechanism described here.

wait for background processes to		
- ·	-	

wait for background processes to	complete. wait: sh(1)
wait: await	completion of process wait(1)
hypot, cabs: Euclidean distance,	complex absolute value hypot(3M)
compress, uncompress, zcat:	compress and expand data compress(1)
pack, pcat, unpack:	compress and expand files pack(1)
and expand data.	compress, uncompress, zcat: compress compress(1)
calculations. vortex: display	computation fluid dynamics vortex(6D)
an image file hist:	compute and display the histogram of . hist(6D)
calendar times INSQUE(3).	compute difference between two difftime:
mkdepend:	compute header file dependencies mkdepend(1)
entry of a common object/ ldtbindex:	compute the index of a symbol table . ldtbindex(3X)
sysmips: MIPS	Computer Systems Inc. system call sysmips(2)
disk driver. dks: Small	Computer Systems Interface (SCSI) . dks(7M)
cat:	concatenate and print files cat(1)
test:	condition evaluation command sh(1)
test:	condition evaluation command test(1)
endif: terminate	conditional csh(1)
fi: terminate	conditional sh(1)
if:	conditional statement csh(1)
	conditional statement sh(1)
while: repeat commands	conditionally csh(1)
until, while: repeat commands	conditionally sh(1)
pathconf, fpathconf: get	configurable pathname variables pathconf(2)
(POSIX). sysconf: get	configurable system variables sysconf(2)
	configuration database master(4)
login: login	configuration file login(4)
resolver: host-address resolver	configuration file resolver(4)
	configuration information table system(4)
usconfig: semaphore and lock arena	configuration operations usconfig(3P)
chkconfig:	configuration state checker chkconfig(1M
lboot:	configure bootable kernel lboot(1M)
parameters. if config:	configure network interface ifconfig(1M)
lpadmin:	configure the LP spooling system lpadmin(1M)
window and request a response.	confirm: display a message in a confirm(1G)
fwtmp, wtmpfix: manipulate	connect accounting records fwtmp(1M)
allow remote printing clients to	connect. addclient: addclient(1M)
socket.	connect: initiate a connection on a connect(2)
getpeemame: get name of	connected peer getpeemame(2
socketpair: create a pair of	connected sockets socketpair(2)
establish an out-going terminal line	connection. dial: dial(3C)
accept: accept a	connection on a socket accept(2)
connect: initiate a	connection on a socket connect(2)
shut down part of a full-duplex	connection. shutdown: shutdown(2)
listen: listen for	connections on a socket listen(2)
acctcon1, acctcon2:	connect-time accounting acctcon(1M)
lvck: check and restore	consistency of logical volumes lvck(1M)
	console: console interface console(7)
console:	console interface console(7)
noiconlogin: select and control	console login program. visuallogin, visuallogin(4)
pandora: login on the graphics	console pandora(1)
MITY	Congotium

header for implementation-specific	constants. limits: file	limits(4)
math: math functions and	constants	math(5)
unistd: file header for symbolic	constants	urustd(4)
mkfs:	construct a file system	mkfs(1M)
execute command. xargs:	construct argument list(s) and	xargs(1)
cps:	construct C to PostScript interface	cps(1)
volume. mklv:	construct or extend a logical	mklv(1M)
remove nroff/troff, tbl, and eqn	constructs. deroff:	deroff(1)
control maximum system resource	consumption. getrlimit, setrlimit:	getrlimit(2)
on. Uutry: try to	contact remote system with debugging	uutry(1M)
List_tape: list the	contents of a given backup tape	list_tape(1)
showsnf: print		
ls: list	contents of directory	ls(1)
cache, cacheflush: flush	contents of instruction and/or data	cacheflush(2)
showmap: display the	contents of the color map	showmap(6D)
savemap: saves the current	contents of the colormap	savemap(1G)
xev: print	contents of X events	xev(1)
csplit:	context split	csplit(1)
•	continue: cycle in loop	csh(1)
	continue: cycle in loop	sh(1)
mpadmin:		mpadmin(1)
arp: address resolution display and	control	arp(1M)
schedetl: scheduler	control call	schedctl(2)
ftimer:	control clock and itimer resolution	ftimer(1)
visuallogin, noiconlogin: select and	control console login program	
ioctl:	control device	ioctl(2)
fcntl: file and descriptor	control	fcntl(2)
init, telinit: process	control iritialization	init(1M)
consumption. getrlimit, setrlimit:	control maximum system resource	getrlimit(2)
icmp: Internet	Control Message Protocol	
newshost: NeWS network security	control	newshost(1)
noiconlogin: login process	control	noiconlogin(5)
msgctl: message	control operations	msgctl(2)
semctl: semaphore	control operations	semctl(2)
shmctl: shared memory	control operations	shmctl(2)
uscillock: lock	control operations	uscillock(3P)
usctlsema: semaphore	control operations	usctlsema(3P)
fcntl: file	_	fcntl(5)
tedrain, teflush, teflow: posix line	control primitives #include int/	tcsendbreak,
xhost: server access	control program for X	xhost(1)
lpc: line printer	control program	lpc(1M)
timedc: timed	control program	timedc(1M)
tcp: Internet Transmission	Control Protocol	tcp(7P)
swapRM, swapINX: floating-point	control registers. /set_fpc_led,	fpc(3C)
sysmp: multiprocessing	control	(0)
closelog, setlogmask, vsyslog:	control system log. /openlog,	
virtually "hangup" the current		vhangup(2)
uadmin: administrative	• .	uadmin(1M)
uadmin: administrative	control	uadmin(2)
uustat: uucp status inquiry and job		uustat(1C)
vc: version		vc(1)
		` .

visuallogin: login process	control	visuallogin(5)
National Instruments VME IEEE-488	controller. gpib: driver for	
ik: Ikon 10088 hardcopy interface	controller	
ts: ISI VME-QIC2/X cartridge tape	controller	
xmt: Xylogics 1/2 inch magnetic tape	controller	` '
ipi, xylipi: Xylogics IPI disk	controllers and driver	` '
ips, dkip: Interphase disk	controllers and driver	
xyl, xyl754: Xylogics disk	controllers and driver	
ethernet: IRIS-4D Series ethernet	controllers	
tty:	controlling terminal interface	
term:		term(5)
units:	conversion program	` '
character classification and	conversion tables. chrtbl: generate	` '
white, tobw:	convert a color image to black and	, ,
terminfo description. captoinfo:	-	captoinfo(1M)
dd:	convert and copy a file	
long integers. 13tol, Itol3:	convert between 3-byte integers and .	
base-64 ASCII string. a641, 164a:	convert between long integer and	` '
/cftime, ascftime, strftime, tzset:	convert date and time to string/	
string. ecvt, fcvt, gcvt:	convert floating-point number to	
scanf, fscanf, sscanf:	convert formatted input	• •
number. strtod, atof:	convert string to double-precision	
strtol, atol, atoi:	convert string to integer	• •
network/ htonl, htons, ntohl, ntohs:	convert values between host and	` '
bmtoa, atobm: bitmap editor and	converter utilities for X. bitmap,	• , ,
X version 10 to version 11 protocol	converter x10tox11:	
simulator and airshow/ dog:	cooperative or competitive flight	` '
dd: convert and	copy a file.	
cpio:	copy file archives in and out	
cp, ln, mv:	copy, link or move files	
rcp: remote file	copy.	•
distep:	copy software distribution	-
uulog, uuname: UNIX-to-UNIX system	copy uucp,	
public UNIX-to-UNIX system file	copy. uuto, uupick:	
copysign, remainder, exponent/	copy sign, drem, finite, logb, scalb:	
copysign, remainder, exponent/	copysign, drem, finite, logb, scalb:	
copysign, drem, finite, logb, scalb:	copysign, remainder, exponent/	` '
copysign, drem, finite, logb, scalb:	copysign, remainder, exponent/	
ftoc: interface between prof and	cord	
executable to facilitate better/	cord: rearranges procedures in an	
terminate current process with a	core dump. abort:	
savecore: save a	core dump of the operating system	` '
	core: format of core image file	
core: format of	core image file.	
mem, kmem, mmem:	core memory.	` '
synchronization of the/ adjtime:	correct the time to allow	* *
fsin, fcos, ftan, fasin,/ sin,	cos, tan, asin, acos, atan, atan2,	
hyperbolic functions. sinh,	cosh, tanh, fsinh, fcosh, ftanh:	
sum: print checksum and block	count of a file.	
we: word	count.	
files.	cp, ln, mv: copy, link or move	
mes.	-r,, orp, , mar or more , , , ,	-L(1)

cpio: format of	cpio archive	
	cpio: copy file archives in and out	
	-	. cpio(4)
/transferdevice for performing		. cpioarchive(1)
transferdevice for performing cpio/	cpioArchive: an interactive	_
		. cpp(1)
interface.	cps: construct C to PostScript	_
unon: run a command on a particular	сри	
clock: report	CPU time used	
display processes having highest		gr_top(1)
display processes having highest		. top(1)
an existing one.	creat: create a new file or rewrite	
	create a file.	
	create a name for a temporary file	
<u> </u>	create a new file or rewrite an	` '
	create a new process	. fork(2)
		sproc(2)
taskcreate:	create a new task

identify processes using a file or	file structure. fuser: fuser(1M)
print checksum and block count of a	file. sum: sum(1)
	file symbol table entry. ldgetname: ldgetname(3X)
symlink: make symbolic link to a	
sys_id: system identification	
	file system backup schedule ckbupscd(1M)
dbg, debug: the debug	file system dbg(4)
0. 0	file system dirview(1G)
<u> </u>	file system fs(4)
	file system identifier fstyp(1M)
	file system independent directory dirent(4)
	file system independent format getdents(2)
	file system information statfs(2)
inode: format of an Extent	
mkfs: construct a	file system
	*
_	file system statistics ustat(2)
	file system status fsstat(1M)
	file system table
	file system type information sysfs(2)
	file system umount(2) file (System V and 4.3BSD), chown chown(2)
chown, change owner and group of a	ille (System v and 4.3BSD). chown, . chown(2)

WorkSpace: graphical interface to	file system	workspace(1G)
fsck, dfsck: check and repair	file systems	
labelit: provide labels for	file systems	labelit(1M)
umountall: mount, unmount multiple	file systems. mountall,	mountall(1M)
tail: deliver the last part of a	file	tail(1)
term: format of compiled term	file	term(4)
utimes: set	file times	utimes(3B)
tmpfile: create a temporary	file	tmpfile(3S)
create a name for a temporary	file. tmpnam, tempnam:	tmpnam(3S)
truncate, ftruncate: truncate a	file to a specified length	truncate(2)
routeprint: route	file to printer	routeprint(1)
access and modification times of a	file. touch: update	touch(1)
ftp: Internet	file transfer program	ftp(1C)
•	file transfer program	tftp(1C)
•		ftpd(1M)
-		tftpd(1M)
	file transport program for the uucp

_	1 0	csh(1)
ferror, feof, clearerr,	fileno: stream status inquiries	` '
search and print process accounting		acctcom(1)
merge or add total accounting	_	acctmerg(1M)
admin: create and administer SCCS link, unlink: link and unlink		admin(1)
cat: concatenate and print	61	link(1M)
-		cat(1)
cmp: compare two		cmp(l)
or reject lines common to two sorted cp, ln, mv: copy, link or move		comm(1)
		cp(1)
dn_ll, dn_netman: 4DDN special filehdr: file header for MIPS object		dn_ll(7)
find: find		filehdr(4)
		find(1)
ident: identify		fspec(4) ident(1)
	files in directories.	٠,
		fsync(2)
		intro(7)
	files istat: print the header	
lockf: record locking on	files	
iocki. Iocold locking on		TOCKT (DC)

nm: name list dump of MIPS object	files mkfontdir: create fonts.dir mkfontdir(1) files nm(1) files or directories. rm(1) files or subsequent lines of one/ paste(1) files. pack, pack(1) files. pr(1) files. rlog: print log messages rlog(1) files. sort(1) files. what(1)
mount, umount: mount and dismount	filesystems mount(1M)
bstream: many buffered more, page: file perusal	filter bstream(1) filter for crt viewing more(1)
	filter for CRTs pg(1)
nl: line numbering	filter
col:	filter reverse line-feeds col(1)
find:	find files find(1)
(6 .) 1' 6	find: find files find(1)
/from the on-line reference manuals;	find manual entries by keyword man(1)
ttyname, isatty: library. lorder:	find name of a terminal
spell, spellin, spellout:	find spelling errors spell(1)
object, or other binary/ strings:	find the printable strings in an strings(1)
the current user. ttyslot:	find the slot in the utmp file of ttyslot(3C)
program.	finger: user information lookup finger(1)
server.	fingerd: remote user information fingerd(1M)
solidview: display the results of a	finite element analysis program solidview(6D)
remainder, exponent/ copysign, drem,	finite, logb, scalb: copysign, copysign(3M)
remainder, exponent/ copysign, drem,	finite, logb, scalb: copysign, ieee(3M)
fold: fold long lines for	finite width output device fold(1)
head: give	first few lines head(1)
setup: initialize system for	first user setup(1)
dbminit, fetch, store, delete,	firstkey, nextkey: data base/ dbm(3B)
xbiff: mailbox	flag for X xbiff(1)
set: set shell flight: simulate the	flags or positional parameters sh(1)
of several aircraft.	flight of any of several aircraft flight(6D) flight: simulate the flight of any flight(6D)
dog: cooperative or competitive	flight simulator and airshow/ dog(6D)
sog. scoperative of competitive	flip: spin one or more objects flip(6D)
/set_fpc_led, swapRM, swapINX:	floating-point control registers fpc(3C)
package TCSETATIR(3T).	floating-point exception handler handle_sigfpes:
ecvt, fcvt, gcvt: convert	floating-point number to string ecvt(3C)
ldexp, modf: manipulate parts of	floating-point numbers. frexp, frexp(3C)
fp_class: classes of IEEE	floating-point values fp_class(3C)
lock on an open file.	flock: apply or remove an advisory flock(3B)
/log 10, log 1p, pow, fexp, fexpm1,	flog, flog10, flog1p: exponential,/ exp(3M)
log1p, pow, fexp, fexpm1, flog,	flog 10, flog 1p: exponential //log 10, exp(3M)
/pow, fexp, fexpm1, flog, flog10,	flog lp: exponential, logarithm / exp(3M)

/fmod, fabs, rint, trunc, ftrunc:	floor, ceiling, remainder, absolute/	floor(3M)
fabs, rint, trunc, ftrunc: floor,/	floor, ffloor, ceil, fceil, fmod,	floor(3M)
smfd: SCSI	floppy disk driver	smfd(7M)
cflow: generate C		
vortex: display computation	fluid dynamics calculations	vortex(6D)
fclose, fflush: close or	flush a stream	fclose(3S)
data cache. cacheflush:	flush contents of instruction and/or	cacheflush(2)
	flyray: a visualized raytracer	flyray(6D)
floor,/ floor, ffloor, ceil, fceil,	fmod, fabs, rint, trunc, ftrunc:	floor(3M)
	fmt: simple text formatter	fmt(1)
width output device.	fold: fold long lines for finite	fold(1)
output device. fold:	fold long lines for finite width	fold(1)

	rcp: remote file copy	. rcp(1C)
/transferdevice for performing	rcp within the WorkSpace	rcpdevice()
transferdevice for performing rcp/	rcpDevice: an interactive	rcpdevice()
	rcs: change RCS file attributes	
resintro: introduction to	RCS commands	rcsintro(1)
	RCS file attributes	
resfile: format of	RCS file	rcsfile(4)
messages and other information about	RCS files. rlog: print log	rlog(l)
ci: check in	RCS revisions	ci(1)
co: check out	RCS revisions	co(1)
resdiff: compare	RCS revisions	rcsdiff(1)
rcsmerge: merge	RCS revisions	rcsmerge(1)
check: check	RCS status of a file	check(1)
	resdiff: compare RCS revisions	rcsdiff(1)
	resfile: format of RCS file	rcsfile(4)
commands.	resintro: introduction to RCS	rcsintro(1)
	resmerge: merge RCS revisions	rcsmerge(1)
	rdist: remote file distribution	
getpass:	read a password	getpass(3C)
	read: accept input from the standard	
of a common object file. ldtbread:	read an indexed symbol table entry	ldtbread(3X)
	read an indexed/named section header	ldshread(3X)
source:	read commands from file	csh(1)
	read commands from file	
	read directory entries and put in a	getdents(2)
	read from file	
WRITEV(3C).	read input to scattered buffers	readv:
	read mail	
line:	read one line	
	read: read from file	read(2)
of an archive file. Idahread:	read the archive header of a member .	ldahread(3X)
object file. ldfhread:	read the file header of a common	ldfhread(3X)

readlink:	read value of a symbolic link readlink(2)
rewinddir, closedir:/ opendir,	readdir, telldir, seekdir, directory(3C)
rewinddir, closedir, dirfd:/	readdir, telldir, seekdir, opendir,
	reader daemon for Bitpad I tabletd(1M)
open a common object file for	reading. ldopen, ldaopen: ldopen(3X)
open: open for	reading or writing open(2)
link.	readlink: read value of a symbolic readlink(2)
read-only.	readonly: make shell variables sh(1)
readonly: make shell variables	read-only sh(1)
group access list (bsd 4.3 version)	READV(3C). initialize initgroups:
and 4.3BSD). Iseek: move	read/write file pointer (System V lseek(2)
stio: routines that provide a binary	read/write interface to the MIPS/ stio(3X)
setregid: set	real and effective group ID setregid(2)
setreuid: set	real and effective user ID's setreuid(2)
	real group, and effective group IDs getuid(2)
	real user, effective user, real/ getuid(2)
allocator, malloc, free,	realloc, calloc: main memory malloc(3C)
fast main memory/ malloc, free,	realloc, calloc, mallopt, mallinfo: malloc(3X)
	real-time display of famous cube cube(6D)
	real-time lighting and shadows light(6D)
	real-time simulation of an idealized . newave(1D)
	real-time simulation of the surface wave(6D)
	rearranges procedures in an cord(1)
·	reboot: reboot the system reboot(1M)
reboot:	reboot the system reboot(1M)
	rebuild the data base for the mail newaliases(1M)
	receive a message from a socket recv(2)
	receive mail mail_bsd(1)
	receive mail via UUCP rmail(1M)
handler.	re_comp, re_exec: regular expression . regex(3B)
	recompute command hash table csh(1)
	record and playback toolchest journalchest(1W
lockf:	record locking on files lockf(3C)
shell. /joumalend: 4Sight event	recording and playback from an IRIX . journalplay(1)
summary from per-process accounting	records. acctems: command acctems(1M)
	records. fwtmp, wtmpfix: fwtmp(1M)
	recv, recvfrom, recvmsg: receive a recv(2)
_	recvfrom, recvmsg: receive a message recv(2)
	recvmsg: receive a message from a recv(2)
	red: text editor ed(1)
	redirect: run a demo with error redirect(6D)
unifdef: strip or	reduce if defs in C code unif def(1)
eval:	re-evaluate shell data csh(1)
	re-evaluate shell data sh(1)
	re_exec: regular expression handler regex(3B)
	reference manuals; find manual/ man(1)
/gather statistics on unaligned	•
	refresh all or part of an X screen xrefresh(1)
	regcmp, regex: compile and execute regcmp(3X)
	regcmp: regular expression compile regcmp(1)
make: maintain, update, and	regenerate groups of programs make(1)

	regex: compile and execute regular	
and match routines.	regexp: regular expression compile	regexp(5)
Centronics-interface/ mkcentpr:	register a color	mkcentpr(1M)
	register a LaserWriter printer with	
address for workstation.	registerinethost: allocate internet	registerinethost(3N)
swapINX: floating-point control	registers. /set_fpc_led, swapRM,	fpc(3C)
routines. regexp:	regular expression compile and match	regexp(5)
regcmp:	regular expression compile	regcmp(1)
re_comp, re_exec:	regular expression handler	regex(3B)
regemp, regex: compile and execute	regular expression	regcmp(3X)
a file for a pattern using full	regular expressions. egrep: search	egrep(1)
table.	rehash: recompute command hash	csh(1)
	reject: allow or prevent LP	
	reject lines common to two sorted	
	relation for an object library	
	relational database operator	
	release blocked signals and wait for .
